The world-wide studies of our Engineers, and our experience in every part of the industrial world, have made possible the development of the SELF-ALIGNING bearing. This same study and experience is at your disposal for the solving of YOUR bearing problems.

Canadian SKF Company, Limited

TORONTO CANADA

You Need a Good Die Stock Set

If you need one at all.

Because a **GOOD** Die Stock Set embodies:

1. Accuracy in its product.
2. Adjustment for wear.
3. Free cutting qualities.
4. Provision for sharpening.
5. Ample adjustment for oversize or undersize.

P. & W. Die Stock Dies **ARE GOOD DIES.**

BETTER than most because of the interchangeable feature in their chasers. A broken chaser in a P. & W. Die doesn't mean a new set of chasers. You can get a new chaser to replace a breakage and the new one "fits in" perfectly in your old set. That's the 6th point, **"ECONOMY IN OPERATION."**

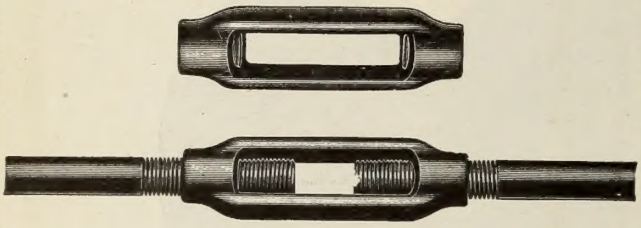
HUNTINGTON STAR DRESSERS

Three Sizes of the Desmond-Huntington

Every workman has a "warm spot" in his heart for good tools. Give him the Desmond-Huntington Dressers. They're the right cutters for quick action. On large, hard grinding wheels they are most effective.



All Desmond-Stephan Cutters are made of the highest grade steel, hardened and toughened. Write for catalogue.

Unusual Jobs at Lower Costs

Shops producing forgings with these powerful machines have many things to say in their favour. Sometimes it is the close gripping dies—the perfect alignment—the ability to work to close dimensions that you hear the men praise. Other times it is the generous gathering capacity—the perfect timing — the all round ease of operation. But one thing you always find is production costs "way down."

ACME

Heading and Forging Machines

Include within their range all kinds of bolts and forgings possible on ordinary Forging Machines as well as many intricate shapes *not possible* on ordinary types. They are practically universal, producing with the same movements bolts and forgings.

Simple, powerful and efficient machines made in a variety of sizes to cover all operations. Besides describing them fully the Acme catalogue deals with Bolt Cutting, Nut Tapping, and other Acme machines. How shall we address your copy?

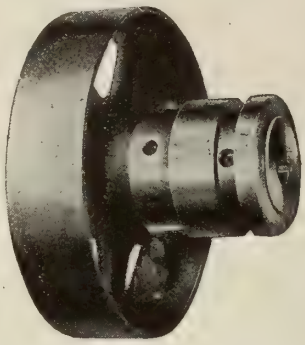
THE JOHNSON FRICTION CLUTCH

Friction Clutches From Stock

Johnson Clutches, both single and double, can now be obtained from stock in our standard slow speed type to fit all common shaft diameters and all standard pulley bores, within the range of light and medium horse powers that we cover.

State definitely —



Just what the clutch must drive.
Actual maximum horse power.
Speed of clutch shaft.
Diameter of shaft.
Diameter, width and bore of pulley.

We Will Select the Proper Clutch and Make Immediate Shipment on All Ordinary Requirements.

Friction Control Means Better Machinery

And the Johnson Clutch is supreme among friction clutches. Adopt it as your standard — always dependable and always promptly obtained.

Complete engineering service to consult on your problems and to handle special installations of any kind.

CUT GEAR COSTS
WITH THE
New Production Gear Shaper

The new production Gear Shaper, illustrated, has been designed to cut gear costs. It incorporates every feature necessary in a gear cutting machine to obtain this result, and still one of the outstanding features of the Gear Shaper principle—accuracy—has been maintained.

It is designed to cut one gear at a time and at a speed which eclipses all other methods.

All operating levers are at the front of the machine, permitting a number to be bolted together and operated as a unit, one 6 H.P. motor furnishing ample power for 10 machines.

It incorporates to the fullest extent the three principal requirements of production—high speed, accuracy and simplicity of operation.

See illustrated article in all technical magazines.

Send for our booklet, "A New Development in Gear Cutting," which has been prepared for the benefit of Engineers and Production Managers interested in the best gear cutting equipment available.

Write for your copy now.

BROWN-BOGGS

B B

Make Sure of the "B-B" Trade Mark

It is a Guarantee of Reliability

The "B-B" trade mark on power presses, shears, tinsmiths' tools and canners' evaporators, and sheet metal working tools of every description, is an iron-clad guarantee that it will give satisfaction on the work for which it is built. And because every tool before it leaves the factory is rigidly tested, we *know* that its merit is beyond question.

We shall be glad to send you catalogs fully describing those machines in which you are interested.

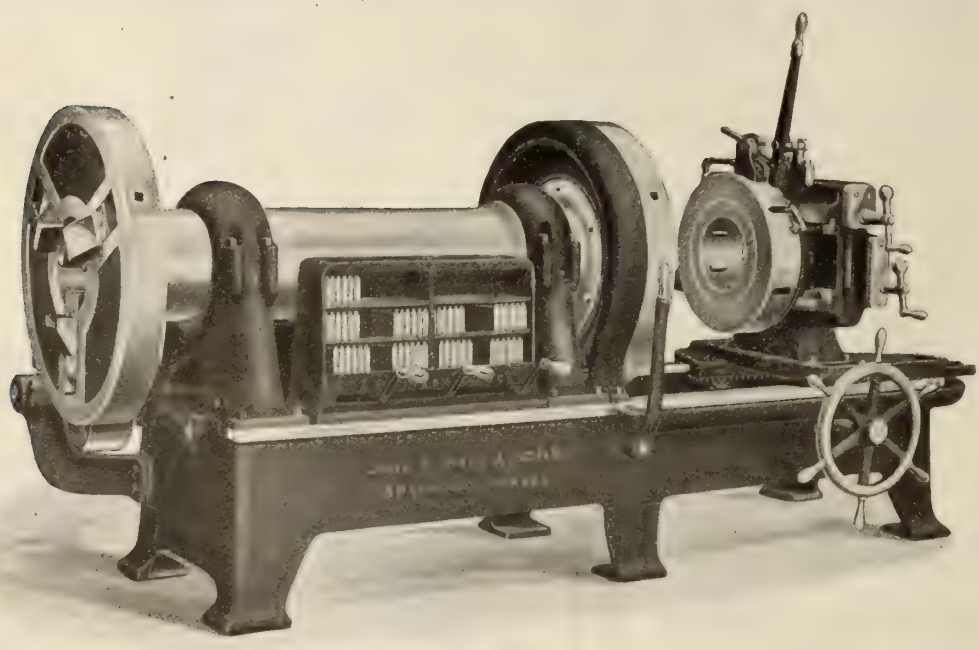
When Canadian Hall Joined with U.S. Williams

A Great Day for Pipe Machine Users

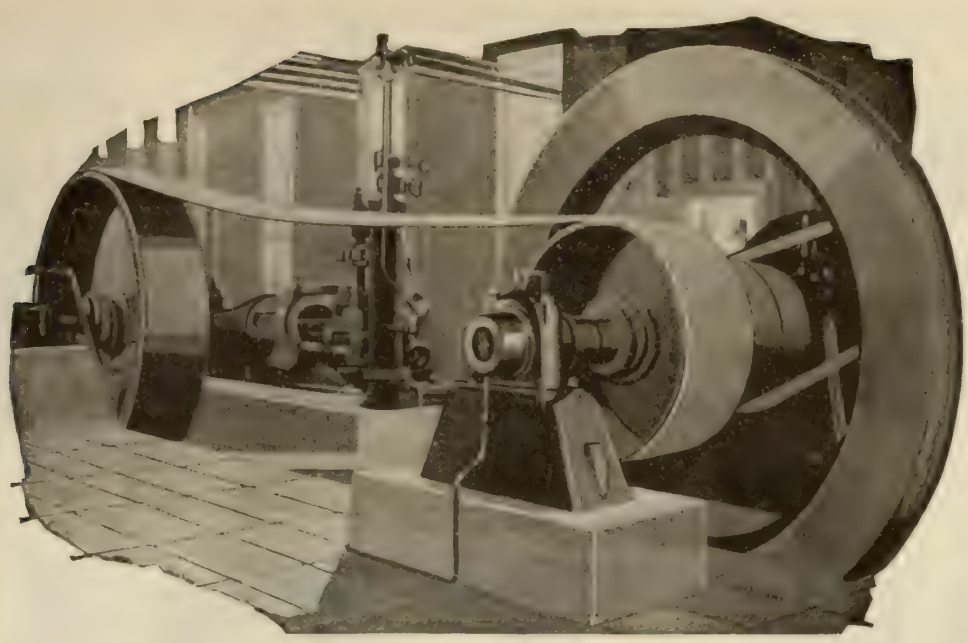
IN CANADA when you think of pipe machines, the name Hall immediately comes to mind. In the United States it's the Williams machine that has won the reputation to thread pipe better, quicker and at lower cost. Now the advantages of both are combined in each. They have joined forces and the Hall is now the Williams of Canada.



Whether it's 1-8 inch or 16 inch pipe or any of the sizes in between, there's a Williams machine just right for the job. Built in eight sizes and each size especially designed to meet the requirements of the case. And remember, each Williams machine is backed by the combined features, experience and service of Hall of Canada and Williams of the United States, each a firmly established leader in its field.

You who do or should use power pipe machines will do well to write for the details of how and why this merger means greater economy, production and efficiency in pipe threading practice.

Ask for the new Williams' handbook "Don't Let It Happen To You."



Williams Tool Corp. of Canada, Ltd.

U. S. Plant: Erie, Pa.

The illustration is of our No. 8 new improved Duplex Type Standard, capacity 2½" to 8" inclusive.

WILLIAMS PIPE MACHINES

The Nearest Approach To Absolute Reliability in Belting Performance

Dominion Friction Surface Belting is the result of the combined experience of all our industrial rubber factories. It is the finished product of the finest materials put together with all the skill of the belt-maker's art. The in-built strength and pulley-gripping power of

Dominion Friction Surface Belting

make it the most dependable and economical for all drives. Every *Dominion Friction Surface Belt* installed means so much power conserved and so much more freedom from troubles due to stretch and slip. It will cost you nothing to have one of our belt experts study your belting problems and submit recommendations for your approval.

has some well established facts to offer - - - - - - - -

You men who have been buying equipment for years know you do not buy machines to look at like beautiful pictures. You buy them for what they will do; and according to how much they will do is their worth determined. In the far-off days when we first started out to win the confidence of Canadian machinery users we figured this out. We also figured that the only way to supply maximum service equipment was to get in touch with the manufacturers of maximum reputation. (Take a look at the firms we represent shown on the left.)

Furthermore we discovered that confidence could not be built up by selling machinery alone. We must sell SERVICE as well. So we engaged some of the best experts we could find at that time. These men have expanded with our business and are always at the service of our clients.

Living up to these principles of QUALITY AND SERVICE has been our biggest asset. To-day we have acres of warehouse space stocked with machinery of all kinds and are in an ideal position to handle rush orders.

We do not intend to depart from our original principles at this late date. Why not see us to-day about required equipment.

GENUINE BRITISH-OAK TANNED

LEATHER BELTING

TRADE MARK

The Sure Sign of Power Saved!

A big percentage of the huge sums of money now wasted on undelivered power can be saved by adopting a really efficient belting—one that puts slippage on the lowest possible figure. In choosing D. K. McLaren's Genuine British Oak Tanned Leather Belting, transmission is placed on the highest efficiency basis. For every D. K. McLaren Belt is made from the flawless backs of the hides of choicest steers—tanned by the famous British Oak-Tanning Process until it becomes so tough and durable that it practically defies wear. Every D. K. McLaren Belt is stamped with the Oak Leaf—the sure sign of power saved. Every belt we have ever sold is giving economy service. Why not let us recommend suitable belt equipment? Write us to-day. It will not obligate you.

Protection From Loss - PHOTOSTAT Prints

You no longer have to send the originals of valuable documents through the mails with the attendant risk of loss. PHOTOSTAT copies can be made in a few minutes at a cost of a few cents each, are perfect facsimiles which require no checking and are accepted as legal evidence in court.

The PHOTOSTAT eliminates the mechanical drudgery of copying by typewriter or longhand. It is used for general office copying of such subjects as letters, telegrams, reports, graphs charts, shipping lists, contracts, ledger pages, insurance records. The PHOTOSTAT copies are photographic facsimiles and so do not have to be read back for errors or checked with the original. You know they are right. An office boy or girl does this work on a PHOTOSTAT after two or three hours' instruction, and in a few minutes and at the cost of a few cents per print.

The PHOTOSTAT also saves many hours in the advertising department, where it is used to reduce illustrations to finished size, to copy layouts, and to determine whether light or dark backgrounds are the more effective. (The original subject can be reproduced either with the same or with reversed black and white values.)

Again the PHOTOSTAT does in a few minutes work that formerly took hours or even days of a tracer's time in the drafting room. It eliminates the necessity of tracing because it copies both pencil sketches, drawings and blue prints.

THE PHOTOSTAT makes no mistakes
(Reg. U. S. Pat. Off.)

It makes photographic facsimiles directly on sensitized paper at original size, enlarged or reduced.

Landis Threading Machines

Competition Proved Them Best

Testing thread-cutting equipment under working conditions is undoubtedly the best way to make a correct choice. So many concerns have picked Landis Threading Machines this way, however, that you are saved the expense. The Wilcox & Crittenden Co., Middletown, Conn., is one of them. "Superior both in construction and operation," says this firm; "all further orders will read 'Landis'."

Photograph shows the threading of turnbuckle rods. First a batch with right hand threads goes through, then a lot of "lefts." Threads are ¾ in. U. S. Standard, 6 in. long. Finishing the last batch, operator assembles the turnbuckle, getting a production of 15 complete per hour.

The latest Landis Catalog should be in the active files of every up-to-date manufacturer. Write for it to-day.

ARE-MAC-DEE IS A GUARANTEE

A Bigger Day's Work

is made possible with McDougall Crank Shapers than with any ordinary Shaper because the McDougall is built on lines especially for this purpose. It embodies the most approved features of the most practical shapers on the market and care has been taken to exclude all non-essential parts.

The column is massive in construction, well braced and reinforced internally. Exceptional strength is also seen in the ram, which is semi-circular in form and of box type. It can be set forward by crank conveniently arranged.

Slides are square, accurately fitted and with broad bearing surfaces.

Have us explain the other salient points of this finely constructed machine. Full details on request.

Hints and Suggestions for Speeding up Filing

Development of File Industry Has Covered Lengthy Period—Different Types of Files and Their Uses——Proper Height of Work To Allow Workman Free Swing of His Arms

*By J. H. MOORE

THE AVERAGE machinist, toolmaker, or in fact anyone using a file, seldom thinks of the development work which has been expended on the product in his hand. To produce a modern file, many operations are entailed, and viewed in the light of the earlier methods of file manufacture, they show great progress. Delving into the early ages we find that the rasp was the forerunner of the later types.

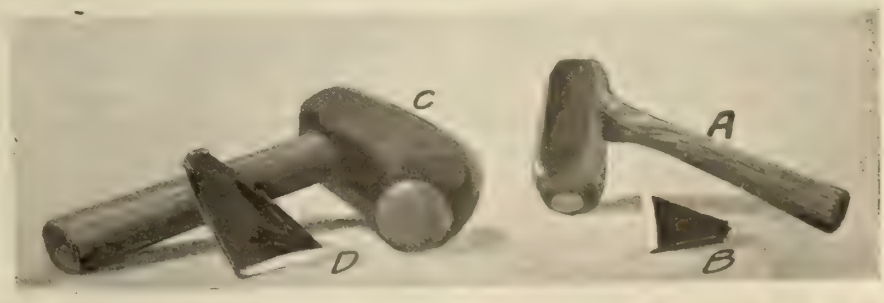
Before iron and steel were even known, man had thought of rubbing away soft surfaces with a harder material than the surface to be rubbed. Nature helped development in this respect, as it provided several so-called rasping surfaces, some of which are still in use among primitive races. For example, there is the skin of the "Dog-Fish," the "Skate Skin," and the tongue of another fish called the "Aropaima Gigas." It is doubtful if many will get their own tongue to pronounce the name of this particular fish tongue, but be that as it may, here is how they used these materials. They wrapped the skins around a stick or flat piece of wood, and while the product was very poor, it served their purpose at that time.

In the Stone Age a new type of rasp was introduced. A flat wooden slab was studded with small pieces of flint, and later an improvement was made to this style by chipping the flint, making an irregular surface. It was not until the Iron Age that the metallic file made its appearance. The Romans are known to have used such files, but as far as can be gathered, files were unknown to the ancient Greeks or Egyptians. History shows that the oldest files of which there is record, were discovered at Chatlet in Champagne during some excavations. These were shaped flat, half round, and square, and as far as can be learned, were cut by hand.

With the increase in the requirements of civilization the uses of the file became amplified. Different types were devised for special purposes. Organ makers in the seventeenth century used a sort of float file with bent tang and point curved upwards. Tin pewterers used a piece of iron 2½ ft. long by 1 in. wide and nearly 1 in. thick, with teeth on both sides about 3/16 in. apart.

In 1795 we find that an English machinist decided that files were too easily worn out, so he patented an "everlasting file," the teeth of which were movable. They could be taken out, placed in a holder and re-sharpened on a grindstone. In all the above cases files were cut by hand, with hammer and chisel, and the illustration with the article shows two of the hammers used during the hand-cutting period.

From the Stone Age to the present time has witnessed so many changes of importance, that it is best to take all this development for granted. Should readers be anxious to read of the modern method of making files they can refer to the Oct. 30th, 1919 issue. Considering only the many styles of files in use to-day let us touch briefly on the terms applied to the different types. When a person speaks about the "Back" of a file, he means the convex side of either a half-round, cabinet, pitsaw, or other file of similar cross-sectional shape. The term "Bellied" is used to describe a file having a fullness in the center, while the word "Blank" is used to describe files in any process of manufacture before being cut.



The term "Blunt" is applied to files which preserve their sectional shape throughout from point to tang, while the expression "Equaling" is used to describe a blunt file upon which is produced an exceedingly slight belly or curvature, extending from point to tang, the file apparently remaining blunt.

The coarser grades of single cut files are quite frequently called "floats," especially when cut for plumbers' use, or for soft metals or wood. Then there is the word "Hopped." This is a term known amongst file makers, and is used to represent a very coarse or open spacing of the teeth, (sometimes, exceeding ½ in.) mostly applied to the backs of half-rounds, and to the edges of quadrangular sections.

The term "Middle Cut" is used to designate the cut of a file when it is of a grade of coarseness between the rough and bastard. It is but little used in this country however. Then there is the "Over Cut," this term being used to describe the first series of teeth on a double cut file.

Re-Cut or Re-Cutting

The above expression means the working over of old or worn out files by the several processes of annealing, grinding out the old teeth, re-cutting, hardening, etc., and thus again preparing them for use. This operation is sometimes repeated two and even three times, but the economy of re-cutting at all is very much questioned, and in some plants, they refuse to use re-cut files of any

Showing two sizes of old style hammer and chisel. These were used when files were cut by hand and the heaviest hammer in illustration weighed ten pounds.

*We are indebted to the Nicholson File Co., Port Hope, for the use of their booklet, "File Filosophy," in the preparing of this article, also to the Ingersoll File Co., Ingersoll, for the illustration of old style hand-cutting tools.

kind whatever, claiming they do not stand up for any length of time.

"Safe edge," or "side," are two terms used to denote that a file has one or more of its edges or sides smooth or uncut, that it may be presented to the work without injury to that portion which does not require to be filed.

The term "Scraping," as applied in machine shops means that this process consists of removing an exceedingly small portion of the wearing surfaces of machinery by means of scrapers, in order to bring these surfaces to a precision and nicety of finish (as determined by the straight edge or surface plate) not attainable by the file or by any other means known to mechanics.

The word "Set" means to file off or blunt the sharp edges or corners of file blanks before and after the first or over cut is made, in order to prevent weakness of the teeth and consequent liability to break when put to use. "Dead Smooth" means a very finely cut file, and in Lancashire, England, they call this type of file "superfine," or super cut." The term "Taper" is used to denote the shape of the file is as distinct from "blunt," and custom has tacked this name on as a short way of designating the "Three Square Handsaw" file. When we speak of an "Up-Cut" we refer to series of teeth superimposed on the over cut series of teeth on a double cut file. So much for general terms; but how can such files be used to best advantage?

Hints and Suggestions

A novice watching a mechanic using a file, might be tempted to exclaim "What an easy task," but would such a remark be true? Very few mechanical operations are more difficult than that of filing well. In the case of the many styles of machine tools, the cutting medium is guided by some definite arrangement, but not so with the file. The human element enters into the matter, the hand being the guiding medium. When you meet a mechanic who can file well, you can safely say, that practice has made perfect, for in his earlier days the mechanic must have practised well. Anyone who has trouble with filing, should take these words to heart and decide to practise. True, it will mean perseverence and patience, but it will pay in the end as accuracy will be secured.

While a perfect file is necessary to secure the best results in filing, the workman's success depends very largely on his ability to select the proper shape and cut of file for the work he has to do, together with generalities that may be given with any idea of practical value to the beginner. The school of experience is where he must acquire the ability to become expert but from the description given later on in this article a general idea may be had that will assist in making the proper selection of the file to use.

A Severe Test in Filing

A severe test in filing would consist in producing a true flat surface upon narrow work, or say that whose width does not exceed one-eighth the length or stroke of the file. To the uninitiated this would seem to require that the file should have a perfectly true and straight surface, but were it practicable to make the file absolutely flat and true, it would then be necessary to move it in absolutely straight lines across the work; even were this operation possible, the pressure, if applied to each end of the file, as is the usual custom, would give it sufficient spring to cause a slight concavity to its cutting surface, and thus an inevitable rounding to the surface of the work must be produced.

Therefore, to produce a flat surface under this severe test, or even under more favorable circumstances, the file should have a convexity given to its surface.

Convexity in Files

Undoubtedly, few, even of the old filers, have given the subject of convexity as it bears upon broad surface filing the thought it is entitled to. It is known to many mechanics that a file which will bite and cling, with the accustomed-downward pressure, upon wrought iron or soft steel will require a greater pressure to prevent it from glazing or slipping over the work, when applied to broad cast iron surfaces. This is owing to the glassy nature and extremely granular formation of these surfaces; consequently the teeth should enter the surface deeper than in the more fibrous metals or they will soon glaze over and become dulled or shiny, thus giving to the file the appearance of being soft, while the contrary may be the fact. Many a well hardened file has been called soft because the operator has failed to give it a fair chance.

Considerable convexity is, therefore, needed in such cases; for while it gives greater control of the file from point to heel, it also presents fewer cutting points to the work with a given pressure downward than the less convex file—the bite being increased in proportion to the increase of the convexity. The ability, therefore, to increase it more or less, at the will of the operator, is of considerable importance.

In finishing many kinds of work, the absence of a suitable convexity limits the usefulness of thefile—as in the preparation of the valves of steam engines, tables of printing presses, stereotype plates, or other work requiring a true surface.

While an absolutely true surface is confessedly unattainable, it is evident that, as in the above cases, a degree of perfection is sometimes desirable beyond what the necessities of other work may require; and to be able to touch the exact spot indicated by the straight edge or surface plate with the file, is to utilize it in a manner which could not be done if the convexity did not exist.

Files Properly Handled

When the proper selection has been made, before using the file it should first of all be properly handled; i.e., a handle of the proper size with the proper size hole, drilled straight, should be fitted to the file, not, as is too often the case, by driving the handle halfway down the tang and thereby doubling the chances of breaking it, but by forcing it well up to the shoulder, thus enabling a suitable grip which is essential to a proper guiding and control of the file. It not infrequently happens that the tang hole is not drilled central or is badly out of line, or does not properly fit the tang of the file; in such cases the tang of an old or worn file of similar dimensions should be heated, taking care, of course, not to draw the temper, and the hole in the handleburned out to nearly the desired size and shape before driving it upon the tang.

Of the many file handles of special construction hitherto devised, there are none which have, as yet, combined that simplicity, utility, and economy necessary to take the place of an ordinary wooden handle conveniently formed and properly ferruled, provided it be firmly affixed and carefully used.

Devices for Holding Files

The file, when used in the ordinary manner, considerably exceeds the length of the work; but when such is not the case, as in filing large table surfaces and shaping out recesses of considerable length, or when, from other causes, the ordinary handle will not answer, it then becomes necessary to grasp the file by holders of special construction. These special devices (many of which are quite crude) are numerous, and vary to suit the particular shape of the file and the work to be performed.

Short pieces of files of special construction are sometimes clamped to the slide rest, to be used upon work revolving in the lathe, and are soldered or screwed to bent handles which require to be used in finishing in and around the bottoms of shallow cavities. The necessity of this last method can be avoided by using a stub file holder, this consisting of a specially constructed handle and which is marketed in the usual way. Wood workers quite frequently clamp one or more files to pieces of board, or fasten them by means of staples and wire pins, or by cutting in, in such a manner as will enable them to smooth out grooves, or true up the edges of their work, using the board or holder as a gauge. Bent rifflers are often used to reach irregular shaped cavities, this really being a file which curves upwards for about one third of its length.

Filing Large Table Surfaces

In filing large table surfaces, the tang is frequently bent upward to admit of the hands clearing the work when the file passes over the surface; sometimes a crank-shaped holder is employed, having one end fitted to receive the handle. These devices, while facilitating somewhat the handling of the file, do not give that perfect control which enables the operator to manipulate it at will,

nor do they aid in governing its convexity.

Improved surface file holders are marketed however which, meet these points, thus enabling a skilful operator to do much of the work with the file which has hitherto been done with the scraper.

Height of Work

For filing in a vise the work should be held as rigidly as possible and the vise jaws should be placed so as to be level with the elbow of the workman, which will be found to range from 40 to 44 inches from the floor—therefore 42 inches may be considered as an average height, best suited for all heights of workmen, when the vise is to be permanently fixed. This position enables the workman to get the full, free swing of his arms from the shoulder; the separate movement of the wrist and elbow should be done away with as much as possible.

If the work to be fitted is small and delicate, requiring simply a movement of the arms, or of one hand and arm alone, the vise should be higher, not only in order that the workman may more closely scrutinize the work but that he may be able to stand more erect.

If the work to be filed is heavy and massive, requiring great muscular effort, its surface should be below the elbow joint, as the operator stands further from his work with his feet separated from 10 to 30 inches, one in advance of the other, and his knees somewhat bent, thus lowering his stature; besides in this class of work, it is desirable to throw the weight of the body upon the file to make it penetrate, and thus, with a comparative fixedness of the arms, to depend largely upon the momentum of the body to shove the file.

Grasping The File

In using the larger files, intended to be operated by both hands, the handle should be grasped in such a manner that its end will fit into and bring up against the fleshy part of the palm below the joint of the little finger, with the thumb lying along the top of the handle in the direction of its length; the ends of the fingers pointing upwards or nearly in the direction of the operator's face.

The point of the file should be grasped by the thumb and first finger, the hand being so held as to bring the thumb, as its ball presses upon the top of the file, in a line with the handle when heavy strokes are required. When a light stroke is wanted, and the pressure demanded becomes less, the thumb and fingers may change their direction until the thumb lies at a right angle, or nearly so, with the length of the file; the positions changing more or less, as may be needed to increase the downward pressure.

In holding the file with one hand, as is often necessary in filing light work, pins, etc., the handle should be grasped as already described, with the exception that the hand should be turned a quarter turn bringing the forefinger on top and lying along the handle nearly in the direction of its length. In this position, the freest action of the hand and wrist may be had upon light work. Amateurs will find that following these directions, the movements of the file will be simplified and made somewhat easier than if grasped at random and without consideration.

Carrying the File

The most natural movement of the hands and arms in filing is to carry the file in circular lines, the several joints of the limbs being the centres of motion; this movement of a convex file apparently give a concavity to the work, but the real tendency, especially on narrow work, is the reverse, owing to the work acting as a fulcrum over which the file moves with more or less of a rocking motion, giving an actual convexity to its surface except when in the hands of a skilful operator. The real aim, therefore, should be to cause the file to depart only so much from a true right line as will be necessary to feel that each inch of its stroke is brought into exact contact with the desired portion of the work; and by thus changing the course of the stroke slightly, thereby preventing "grooving," a more even surface results and the work is completed sooner. The movements here referred to have reference to those in which both hands are used upon flat work, requiring nicety and trueness of finish, and the difficulties to be overcome in producing even a comparatively true surface with a file require much practice on the part of the operator.

In filing ovals and irregular forms, the movements, while not considered so difficult or trying, nevertheless require considerable experience and a good eye, so to blend the strokes of the file upon the round or curved surfaces as to give the best effect; the varied nature of the work upon this class of surfaces, though much might be said, prevents any detailed definition as to these movements of the file within the limit of this article.

In point of economy, the pressure on the file should be relieved during the back stroke; this will be apparent to anyone who will examine the formation of the points of the teeth, when it will be seen that the file can only cut during the ordinary or advancing stroke and that equal pressure during the back stroke must be very damaging to the points of the teeth.

We do not wish to make this article of undue length, yet there are many other important points which should be considered if good filing is to result. We believe readers will be vitally interested in the points discussed in the conclusion of this article which will appear in the next issue. Watch out for it, as it will speak on the lathe work, drawfiling, preparing work, when oil may be used on a file, etc.

NEW MINE RESCUE APPARATUS

Ever since the invention of the Miner's Safety Lamp by Humphry Davy, Great Britain has devoted keen attention to the subject of safety devices in mines. Experiments recently conducted by the British Scientific and Industrial Research Department have resulted in the design of two new types of rescue apparatus which are proving most successful. Both types of apparatus are what is known as "regenerative"; that is to say, the air expelled by the lungs is purified, supplied with oxygen, and returned to the lungs. Therefore, when a man wears this apparatus he is able to enter smoke or poisonous atmosphere without suffering ill effects. The apparatus and the lungs really form a closed circuit, and the lungs serve as a pump to circulate the air round that circuit. In one type of apparatus the oxygen is supplied from liquid air and in the other type it is obtained from a solution of compressed gas. Both pieces of apparatus are designed to enable the wearer to undertake continuous heavy physical exertion for at least two hours. As a matter of experience they can satisfy all the breathing needs of the wearer for three hours.

When it comes to area Canada is entitled to say something. It covers the vast stretch of 3,729,665 square miles, which is equal in area to the United States with Alaska, the Philippines and all other possessions. Its population, however, is as yet no larger than that of New York and Chicago cities.

The Selection and Training of Salesmen

This Branch of Business Management is of the Greatest Importance—Many Men Have Wisdom But Do Not Know How to Apply It—Prosperity Depends Upon Our Own Efforts

By F. E. MUTTON
President and General Manager International Business Machines Co.

ONE of the major problems facing Sales Managers to-day is building up an efficient sales force to secure orders. Sales organizations are being subjected to the acid test; some of them will fail to survive that test. We have passed through four or five years recently when men who were called Salesmen did not have to sell at all; they became very soft in their ideas of work, yet they made wonderful sales records. Now times have changed; order-takers are of no use now.

We have seventy-two salesmen in our Canadian organization, we reach from one ocean to the other, and have offices and service stations in all cities and large towns.

Get Down To Hard Work

It has occurred to me during the last six months to a year, carrying our share of worry as to business conditions, that there are many men who have got a lot of wisdom but do not know how to apply it. They do not realize the vital application of it, and that is the hardest kind of work. Especially salesmen who have had five years of easy going, it is hard to realize that they have got to get down to hard work or they will not stay in a sales organization very long.

Of course I recognize that a sales organization selling a specialty like Time Recorders or Scales is different from one selling a standard article, however, I believe the same fundamental principles apply, and that this matter of selecting and training salesmen is the most important factor facing executives of any concern to-day. It is the salesmen that keep the factory chimney smoking, and the amount of smoke depends on the efficiency of the sales-organization, absolutely.

The New Conditions

The quicker we all realize that prosperity depends on the action of our own self-starter the better. A good many people are just waiting for something to turn up, even sales managers. To my mind there is nothing "going to happen" until you make it. Instead of the men going out on the 9 o'clock train they will have to go on the 7 o'clock if they are to succeed, and instead of coming in Thursday night or Friday noon, they will come in Saturday morning—if they are lucky. Those are the new conditions that we are facing.

I want to convey this idea; it is not necessary to tell most men these things, it is necessary to "sell" them. In our organization we never tell a salesman to do something. We "sell" the proposition. That is the only way to get the proper co-operation and spirit. The art of selling is the art of buying. What do I mean?—well, the amount you sell depends on the amount of confidence you can buy, the respect you can buy from the prospective customer. I think that it is an important principle to have the sales force memorize.

Obtaining Sa'esmen

Now where are we going to get our salesmen? Our experience is that we

F. E. MUTTON.

get our best men through our present sales force. Those men know the policy of the company, they have confidence in the company, they know the calibre of men the company want, and they have seen in action the men that they are going to send in to apply for the position. That is something you cannot do as a general proposition. They know whether he plays pool in the hotel until 2 a.m. or poker until daylight. They know his characteristics through working with him. I emphasize that, because looking back over my experience during the last thirty years I find that the best salesmen it has been my good fortune to secure came through the salesmen we already had.

You will not buy an automobile unless you try it out, but there are many hundreds of salesmen employed by sales managers who have never seen them in action. A man comes to your office, naturally he is at his best, but that does not tell you what he will look like in Peterboro or Montreal or Vancouver. His nails are clean and his shoes are shined. We did the same ourselves years ago. The important thing is to see the man in action in his regular working form, day in and day out, get a line on his characteristics, how he stands up under the test of the three a.m. bus, and the one old kind of pie, and no cream.

The Other Fellow's Salesman

The next channel is from the salesmen that canvass you for orders; and that is a good channel. "Do you mean to tell me you woud deliberately employ one of my salesmen?" someone may ask; I certainly do. If you say that is not a fair proposition I do not get your point of view. If my salesmen can make more money with you they will go with you. Therefore I am never too busy to see a canvassing salesman. The bank manager can wait, but this man may be the one I need as the corner-stone to a certain portion of our sales force.

I believe the successful sales manager is the man who is never too busy to see a canvassing salesman. If I am in a conference which would make it necessary to keep him too long, I go out and see him for a moment and apologize and make an appointment.

I spent twenty years with the National Cash Register Co. Mr. Paterson the President of that company, is known as a wonderful leader. We were in a convention of the sixteen sales managers of the North American Continent. Mr. Paterson came in and remarked: "These are the Sales Managers, yes; now just what do you gentlemen do for the high salaries you get?"

Well, it was kind of sudden. One chap stood up and said, "I keep my eye on the territory, I see that the offices are kept nice and clean."

"And you?"

"I check up the accounts and payments and consignments—"

Well, I was thinking fast, it was coming close to me, I said to myself, "these boys are not thinking right," so when he came to me I said, "I employ and train salesmen. I was with the N. C. R. for twenty years."

Looking Them Over

I would have lost the opportunity to secure excellent men if I had been too busy to see salesmen. Often a man has come in and although I did not need him at all, he made an impression. I talked to him fifteen or twenty minutes, asked if he would mind coming in again day after to-morrow—next week,—I wanted to get another slant on him. They never act exactly the same twice in succession. I asked him — "Now just tell me how much money you make and how much you would like to make. It may be that you are fitted for this business. I

am going to find out in the next fifteen minutes if you are."

From the Retail Store

Another channel is the retail store. We have secured some excellent men who were retail store clerks. There is a field where you will find ambition; also, it is a field where men are not over-paid. An illustration; we had difficulty in getting our devices in retail stores. Our time-recording division salesmen had been trained to interview manufacturers and factory men, but they fell down on the stores. I discovered that they did not know the language of the retail merchant, they had never been in that atmosphere. I looked about and found a young man who was head clerk in one of the large hardware stores in Hamilton, snappy, well-dressed, knew his job or he would not have been head clerk. I brought him to Toronto and employed him. We had to teach him the time-clock business as it related to the retail store; I said to him, "Now you will have to go into the factory and put on a pair of blue jeans and work from 7 till 5.30 for two weeks, for which you will not get any pay."

"All right," he said, proving his mettle.

I was only testing him really, but that was his mechanical training. The first month that young man was out in the Hamilton territory he sold eighteen machines to eighteen stores. That was good work. He knew the atmosphere and the language.

The weakest source is advertising for salesmen. I do not believe it is good business or sound policy to hire a man who is out of a job. That, perhaps, sounds severe, but there is generally some reason why he is out of a job, and it is difficult to get at the true reason. If you are going to put up a "Safety First" sign get a salesman who is in a position.

"The Bible"

Now, I want to put before you in this graphic way, these principles:

Get them clean —Mentally —Physically —Morally —Spiritually

That to me is "The Bible" in hiring Salesmen. There is no one of those things that you can afford to overlook. And you can test them all out in your interviewing.

Mentally.—The salesman who will consume time telling those stories that we sometimes hear is not clean mentally. The results show physically and morally.

Spiritually.—This is very important. Sometimes we meet a man who does not believe in such things as churches. I am not preaching a sermon, but I know the value of that element, we all do.

Then I would like to add Keep Them Clean as to the environment they live in.

Organization

In my opinion the following elements come under the head of organization in a sales force.

Employing Men
Training Men
Supervising Men
Promoting Men
Firing Men

If we are capable of the first four, we will not have to worry about the last.

As to qualifications, here they are:—

Health
Character
Deportment
Reputation in Own Neighborhood
Guarantee Bond
Manner
Ambition
Confidence in Himself

I have a chart on my desk and that is always ticked off 100 per cent. before a man is taken into our organization. Health is most important. If a man has not got 100 per cent, health he is anchored. A lot of talks have been made on Salesmanship; to me Salesmanship is the combination of a lot of qualities. Health is the foundation.

Our company spends a good many dollars a year in taking care of the health of our organization. We talk to them of what to wear, what to eat, etc. A lot is wasted, but some gets home and it does a lot of good. I venture to say when you meet one of our salesmen you find he is "in the pink." If he is not, he will not go out, they are trained not to.

Foundation of Everything

When a salesman approaches a prospect, one of the most important elements in getting that man's order is the salesman's health. Selling is largely a matter of domination. You need all the health and energy at your command to dominate some people; if you are only feeling about 70 or 80 per cent. fit, the buyer will do the dominating. Health is the foundation of everything. Take personality, the salesman's greatest asset. You cannot see personality, you just sense it. It is a thing you cannot define, and the greatest element of personality is health His eyes are bright and his step springy and he thinks just a little faster than his prospect; he cannot do it unless he has 100 per cent. health.

Supervision

Then supervision. I think lack of supervision is one of the weak links in our work. Every man needs it. Let me illustrate. The chain is—

Salesmen
Sales Agents
District Managers
Sales Managers
General Managers
President

Does it stop there? No, it goes on—

Executive Committee
Directors
Shareholders

I would like to make this subject clear.

Who supervises Salesmen? The Sales Agents.

Who supervises the Sales Agents? The District Managers.

Who supervises the District Managers? The Sales Manager.

Who supervises the Sales Managers? The General Manager.

Who supervises the General Manager? The President.

Who supervises the President? The Executive Committee.

Who supervises the Executive Committee? The Directors.

Then last, but not least, who supervises the Directors? The Shareholders.

Enthusiasm Injections

One of the reasons salesmen fall down is because they are not supervised closely enough. I do not mean bossed. We do not know the meaning of "Boss" in our organisation.

Supervision means, for one thing, that you get out with the salesmen occasionally, especially the men in the Provincial territory, who are meeting to-day probably the greatest resistance in the history of trade in this country. They are only human, they get lonesome, they have gone a week perhaps without an order. The greatest asset for a salesman to have is a big stout heart, not knowing the meaning of "Quit." Well, that man needs supervision it might be termed, or Assistance, a new injection of Enthusiasm, which he can only get from an executive higher up.

I have recently returned from a trip to the Coast. I am running the manufacturing end as well as the selling end, but there is nothing else so important to my mind as going out and visiting these men, spending a day or two or three with them, getting that heart-to-heart touch that they appreciate so much—I know it because I have been there and received that treatment.

Necessity For Training

As to training. How many firms do not seem to realize its necessity? I have had men come to me who seem to have been given a price list and an order book, and left to grab any further knowledge they could out of the atmosphere. Those salesmen are going to run up against other men in parallel lines who have been trained, and we have got to see to it that our men are equipped to meet these trained men. If in your own judgment the new salesman is the right material for your organization, then it is worth spending time and money to give him the proper ammunition.

Peddling Troubles

It is important to train salesmen to know that it is no earthly use telling their troubles to fellow salesmen.

To salesmen I say, if you do not agree with the policy of the house, don't go to Bill Jones about it, he cannot cure it; go to the General Manager, and if he does not satisfy you, go to the President.

Get your men to have enough confidence in you and the house to know that they can do that. Many good sales organizations are wrecked by "gossip" breeding disloyalty, so have them feel that if they think they have any complaint they can come to you, and either they will "sell" you that they are right or you will "sell" them that they are wrong.

"People are only suspicious of things they do not understand." It is of primary importance in training salesmen that they should know and thoroughly understand the policy of the house. Then it will have their support.

Constructive Help

One of the chief duties of the Sales Manager is to give his men constructive help in their work. If a sales manager cannot help his salesmen make sales, what is he for? I have three sales managers in my business, one for each division. Each of them when he visits an agency helps the man there to make sales. If he could not he would not be the sales manager. I do not mean for him to go out and canvass the stores, I mean he is everlastingly gathering material and thinking, so that he has something to take out with him and say "Put this down in your note book."

A Talk On Cards

I have a little talk on cards for our salesmen. I am a great believer in teaching through the eye. Some of these cards are:

Success is Simple. You can talk five minutes on that to a Convention.

Service. Action of one on behalf of another in the interest of both.

Add Yourself Up. Don't overlook the weak spot—we all have a lot of them.

Think In Big Figures. Teach the salesman who is selling two thousand to think of ten thousand.

We Are Only As Big As We Think. Let him look at that a minute.

Increase Health and Knowledge. The salesman can never afford to stop doing that.

Men Make the Business. You can take the biggest concern in Canada and burn down the whole institution, and they could collect insurance and build up again, but if you took my seventy-two salesmen I would have some job to get things going again. Trained men are of more value than machinery and plant. Let them know how much you value them.

Teach Salesmen Not To Guess, to know what they are talking about.

Cut Out Gossip, Fault-Finding and Destructive Criticism. What is wanted is Constructive Criticism.

A Man Is Known By The Company He Keeps, And A Company Is Known By The Men It Keeps.

The Open Mind is The Growing Mind.

Men Should Not Be Employed At Any Task Which a Machine Can Perform.

Self Analysis. Teach the Salesman to analyze himself, the most helpful thing he can do.

Better To Aim At Perfection and Miss Than Aim at Imperfection and Hit It.

Organize The Brains of Your Organization.

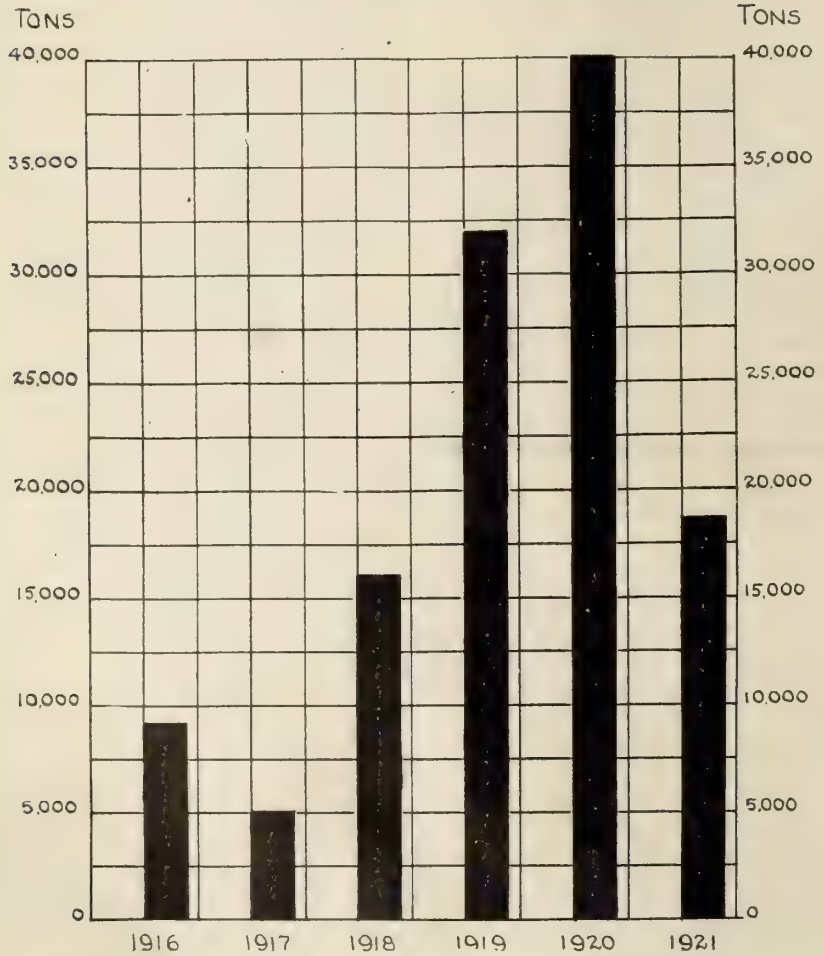
Don't Make The Same Mistake Twice! But If You Never Make Any Mistakes You Are No Good.

Co-operation.

Concentration on the work you are doing.

Study, Learn and Teach.

Think.



Tell Your Griefs to the Man Who Can Help You.

Through The Eye

The purpose of these cards that I use at Conventions, and further that I distribute around our factory and office is to educate the Organization through the eye, and at Conventions you will find the salesmen copying them down in their note book, in other words, they are gathering ammunition that is going to help them at some time.

The Sales Manager who can select the proper men and train them properly will never have to look for a lucrative position. The position is looking for him.

EXPORTS OF PULP FROM CANADA TO JAPAN.

CONDITIONS IMPROVED

Mr. F. W. Field, British Government Trade Commissioner in Toronto, has just finished an extensive trip to most of the industrial centres of Ontario for the purpose of securing first hand knowledge of the industrial situation and its outlook. He interviewed one hundred and fifty manufacturers, heads of departmental stores, principals of wholesale houses and others. He finds that business throughout the Province is comparatively quiet but he is gratified to learn that it is slowly improving. His opinion, based upon what he learned, is that the worst of the trade depression is over. Within a year, he states, the country should be enjoying a more normal time.

SOME SMASH

There is a story going the rounds about a Scotsman, who, anxious as usual to "make a little on the side," hit upon the idea of collecting old tin cans and pieces of scrap iron. Having accumulated a good collection he sent them to a local junk store.

Somehow or other, however, they went astray and were delivered to the wrong place. Imagine his suprise when he received the following letter from a garage:

"Dear Sir,—Your motor car to hand. We have never seen a worse smash, but we will do our best to put it together again. We send you herewith an estimate for the cost of repair and approximate date of delivery."

Standard Specification for Wire Rope

Requirements for Grades of Wire Rope for Mining—Dredging and Similar Purposes—Points Emphasized Are Regarded As Essential to Protect Both Purchaser and Manufacturer

By C. A. S. E.

VERY CREDITABLE work has been done by the Canadian Engineering Standards Association, in establishing standard specifications on various classes of goods. They have now issued a standard for wire rope for mine hoisting and hauling purposes; dredging and steam shovel work, and feeling sure readers will be interested in the details, we publish the points contained in the new specifications.

It was at first considered that separate specifications should be prepared for rope for mining, and for rope for dredging, etc., but on examination, the governing conditions for both kinds of work were found to be so far in agreement, that the specifications were combined. The classification of material adopted, recognizing three grades of steel, is in accordance with the practice now used in Canada. At the desire of the manufacturers' representatives on the Committee, the customary term "Crucible Cast Steel" has been retained as the description of a particular grade of material, although the Committee realizes that its employment is not in accordance with metallurgical usage.

Rope made under the new specification will be known as C. E. S. A. standard hauling rope as the case may be.

At the time of placing the order the purchaser will furnish to the vendor all necessary information regarding the conditions under which the rope is to be used, and the kind of service for which it is to be employed, together with other particulars, as enumerated in Appendix I. In tendering, the vendor will furnish the purchaser with information regarding the construction of the rope which he proposes to supply, as set forth in Appendix II, and shall, at the same time, furnish a written guarantee regarding the ultimate tensile strength of the finished rope.

The term "vendor" throughout this specification shall mean the seller of the wire rope, whether he be the manufacturer of the rope or not.

Grades Of Material

The following shall be the recognized grades for material for wire for C. E. S. A. standard ropes; Crucible Cast Steel; Plough Steel; Special Plough Steel.

The term "Crucible Cast Steel," as here used, is intended to imply an acid or basis open-hearth or bessemer steel of medium carbon content.

The terms "Plough Steel" and "Special Plough Steel" as here used, are intended to imply a high grade acid open-hearth steel somewhat higher in tensile strength than the Crucible Cast Steel, and of higher carbon content, say, 0.50 and upwards. Three grades of material, as here classified, shall be such that the wire made from them will have the following ranges of tensile strength:

Crucible Cast Steel, 160,000 to 210,000 lbs. per sq. inch.

Plough Steel, 200,000 to 230,000 lbs. per sq. inch.

Special Plough Steel, 200,000 to 270,000 lbs. per sq. inch.

Methods of manufacture of the wire itself, of the strands, and of the completed rope, shall be such as to ensure that the finished product will conform to all the requirements hereinafter specified. The wire shall be drawn from mild homogeneous steel, shall be uniformly heat-treated, and, if galvanized rope is required, shall be effectively galvanized as specified below under "Galvanizing."

The rope shall be laid up evenly and uniformly throughout as regards size, and shall show evidence of proper and uniform tension on the strands during manufacture. The number of wires and strands, and the angle and lay of wires and strands shall be as approved by the purchaser. If the construction of the rope is such as to call for filler wires, these, if of different material to the other wires of strands, shall not be considered as contributing to the strength of the rope. Joints in wires composing the strands shall be distributed as widely apart as possible, and in no case shall more than one such joint occur in a length of 50 feet of strand. The use of tucked joints is not recommended.

Lengthening of a strand after manufacture to make it suitable for use in laying up a rope longer than originally intended will not be permitted. The central core of the rope, unless of wire, and the cores of the several strands, if used, shall be of Manilla or New Zealand hemp. Jute cores will not be accepted. The cores shall be carefully laid up, shall effectively support the strands or wires, and shall be thoroughly impregnated during the manufacture of the rope with a preservative mixture which will have no injurious effect on the wires or the material of the cores.

Lubrication of Rope

Both the individual strands, and the rope, while being laid up shall be thoroughly impregnated with a suitable lubricating compound which shall have no injurious effect on the wires or the material of the cores, shall not gum, and shall be of the proper consistency to be retained in the interstices of the strand or rope. When the rope is purchased by weight, the purchaser shall be satisfied that no excess preservative or lubricant composition has been used. If galvanized rope is required, the galvanizing shall consist of a continuous coating of pure zinc of uniform thickness, which shall adhere to the wire and shall present a smooth surface.

Dredging calls for the use of reliable wire rope.

Physical Properties and Tests for Wire

The ultimate tensile strength of the wire shall comply with the following minimum requirements:

Crucible Cast Steel, lbs. per sq. inch 160,000.

Plough Steel lbs. per sq. inch 200,000.

Special Plough Steel, lbs. per sq. inch 220,000.

and shall in no case be less than the values stated by the vendor in his tender for the sizes to be used.

For the purpose of computing the ultimate tensile strength of wire for galvanized rope, the effective cross section of the wire shall be taken as 90 per cent. of the gross area of cross section including that of the zinc coating. The tensile strength of the wire shall be determined by means of a testing machine approved by the purchaser. Samples for the tensile tests of wire shall be not less than fifteen inches long and free from bends and kinks.

The wire shall be cylindrical and smooth, and its diameter (after galvanizing, if galvanized wire is called for) shall be uniform within the following limits:

	Tolerance Above Nom. Dia.	Below Nom. Dia.
Nominal Diameter		
.064 in. and larger	+ .005 in.	Nil
Below .064 in.	+ .003 in.	Nil

The diameter of the wire shall be determined by gauging with a micrometer at at least three places on each coil. The size of wire shall in all cases be expressed in decimals of an inch, using not more than three places of decimals, that is, in mils. Wire which measures below the nominal diameter will not be accepted.

A sample from each coil of the wire (after galvanizing, if galvanized wire is called for) shall be tested in torsion and shall withstand without breaking or showing any signs of splitting or other defect in the wire itself, a number of complete turns not less than the number given by the following table:

Kind of Wire	Turns per length of 100 diameters
Galvanized	15
Ungalvanized	25

In the case of wire for galvanized rope, this torsion test shall not be construed as in any sense a test of the galvanizing. The torsion tests shall be made as follows: The piece of wire shall be gripped by two vises, one of which shall be stationary, while the other shall be free to move longitudinally, and shall be rotated steadily at a speed not exceeding one revolution per second. The full number of twists shall be distinctly visible between the vises.

Samples for torsion tests shall be straight and not less than ten inches long. All tests, as specified above, shall be made upon fair samples, which may be selected by the purchaser's inspector or authorized representative from any portion of any coil of wire.

APPENDIX I.

Information to be furnished by the purchaser to the vendor.

1. Purpose for which rope is required.
2. Length of rope required.
3. Size (diameter or circumference), desired.
4. Grade of material desired { Crucible Cast Steel. / Plough Steel / Special Plough Steel
5. Lay (Regular or Lang's) desired.
6. Whether right or left lay.
7. Whether galvanized or not.
8. Maximum running speed.
9. Maximum working load.
10. Diameter of smallest sheave over which rope will run.
11. Form and dimensions of groove in sheaves.
12. Nature and arrangement of lining material in groove (if any).
13. Whether subject to reversed bending in operation; if so, sketch showing arrangement and diameters of sheaves is to be given.
14. If to be wound on drum, minimum diameter of same, and number of layers of rope.
15. Whether to be delivered on reels or in coils.
16. Whether all tests will be made at Manufacturer's works before shipment.

When samples of wire are taken from the coils before the rope is manufactured, such samples shall be taken from not more than 10 per cent. of the total number of coils, and tensile and torsion tests shall be made thereon as specified above under "Ultimate Tensile Strength of Wire" and "Torsion Tests of Wire."

Samples From Finished Rope

When finished rope is offered for sale by the vendor and it is therefore impossible to carry out the tests specified above on the wire before it is laid up into strand, the inspector may select the necessary samples of wire from the finished rope, cut from such portions of any length of rope as may be agreed upon between the vendor and the purchaser, and one set of tests as specified above shall then be carried out upon the wire taken from each length.

If, upon testing a sample of wire from any coil of wire or length of rope, that sample is found not to fulfil one or both of tests specified above, similar tests upon two additional samples from the same coil or length, samples fulfill the test or tests, the lot of wire or rope which they represent shall be accepted. If either of the additional samples fail, further tests may be at the discretion of the inspector, on samples from other coils or lengths of the same lot, and the purchaser may accept such coils at his discretion.

Physical Properties and Tests For Rope

The diameter of the rope when delivered, as measured over the extreme outside wires, shall in no case be less than the nominal size, and shall not exceed same by more than 3-32 of an inch in the case of rope one inch diameter and larger, or by more than 1-16 inch in ropes of diameter smaller than one inch.

The ultimate tensile strength of finished rope shall in no case be less than that guaranteed by the vendor.

Check tests of the tensile strength of samples of the finished rope may be made by the purchaser at his own expense, and if so made, shall be carried out on specimens prepared in accordance with the method set forth in Appendix III. Failure in these tests to meet the vendor's guarantee shall be cause for rejection. The vendor shall if required furnish free of cost a copy of any document in his possession showing the results of any tests made for him or for any other person on the rope, or on the material for the rope, sold or offered for sale to the purchaser.

He shall also, if required at the time of purchase, furnish free of cost a certificate that the rope or the material for the rope has been tested, and that such tests comply in all respects with the requirements of this specification. The furnishing of such copies of documents, or the giving of such certificate, shall not preclude the purchaser from rejecting any rope which does not comply with this specification.

Standard Constructions

The following are recognized as standard constructions for C.E.S.A. Standard Wire Rope:

Hoisting	Haulage
6 x 19	6 x 7
6 x 19 Seale type	6 x 12
6 x 37	6 x 19 Seale type

The wire shall be free from scales, flaws, inequalities, splints, and all injurious defects, and shall be of smooth uniform finish. The completed rope shall be free from injurious defects, evenly laid, and free from kinks, loose wires, open strands, or other irregularities, and shall remain in this condition when unwound from the reel or coil, or bent around a standard thimble, provided that proper precautions are taken, and the ends are properly secured.

All rope shall be furnished on reels unless otherwise specified by the purchaser, and shall be suitably protected to avoid damage in shipment. A metal tag shall be securely attached to each reel or coil and stamped with the maker's name, diameter of rope, grade of material, weight of rope, length of rope, and C. E. S. A. distinguishing mark.

APPENDIX II.

Information to be furnished with his tender by the vendor to the purchaser.

1. Grade of material of wires, and of filling wires (if any).
2. Size of rope.
3. Number of strands.
4. Number of wires in strand.
5. Nominal size of wires and filling wires (if any).
6. Nature of material of core.
7. Nominal weight in pounds per foot of rope.
8. Ultimate tensile strength of wire (to be stated for each size of wire used).
9. Guaranteed ultimate tensile strength of completed rope.
10. Location and particulars of testing machine available for tensile tests of wire.
11. Gross weight of rope as packed for shipment.

Inspection and Rejection

The inspector, representing the purchaser, shall have free entry at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works which concern the manufacture of the rope ordered. The manufacturer shall afford the inspector, free of cost, all reasonable facilities to satisfy him that the wire and the rope is being furnished in accordance with this specification. All tests and inspection shall be made at the place of manufacture of the rope, and prior to shipment, unless otherwise specified by the purchaser, and shall be so conducted as not to interfere unnecessarily with the operation of the manufacturer's works.

The manufacturer shall provide at his works, free of cost, all apparatus and labor for making the required tests under the supervision of the purchaser or his inspector. This requirement shall not apply to the tests specified above under "Tensile tests on fiinished rope." Rope which does not conform to all requirements of this specification will be rejected.

APPENDIX III

THE TEST pieces for tensile tests on completed rope must be free from initial bends and preferably not less than eighty inches in length between sockets. In preparing the test specimens for socketing, at least two seizings or servings of soft iron wire, each about one and one-half inches long, are placed tightly upon the rope at a distance apart equal to the intended length of the test specimen between sockets. Two similar additional seizings are placed beyond the first two and at a distance from the first equal to the length of the socket, this length being from five to nine inches in a range of diameter of rope of say one-half inch and one and one-half inches.

It is most important that proper seizings shall be placed at each side of any point at which the rope is to be cut. If possible two, or, better, three, seizings should be employed at each side of a cut. Annealed iron wire should be used, the suitable sizes being from .054 diameter for rope one-half inch diameter up to .080 for rope one inch diameter and .105 for rope two inches diameter.

After the specimen is served as described, it is cut from the coil of rope, and each end is slipped into a cast steel or forged steel socket, the outer dimensions of which suit the holders of the testing machine to be employed. The inner surface of the socket is conical, with taper of about one in four on the diameter. The ends of specimen are next to be broomed out and secured in the sockets, as follows:

Core of Rope Removed

After the sockets are placed on the specimen, it is clamped in a vise, the end serving wire removed, and the strands and wires carefully opened or frayed out as far as the second serving. The core of the rope is removed for a distance equal to the length of the socket. Individual wires are next thoroughly cleaned with waste and the free use of gasoline, and are then carefully wiped to ensure their freedom from any trace of oil which may occasion slipping of wires in the zinc filling. If the rope contains much lubricant, it may be desirable first to wash the frayed-out portion in caustic soda solution, but this is not necessary when the lubricant is carefully removed and the wire thoroughly cleaned with gasoline. A portion of the wires may be bent back on themselves at the ends for an inch or two in order to ensure a good bond in the zinc.

If difficulty is found in obtaining proper adhesion of the zinc filling to the wires, the wires, after cleaning with gasoline and wiping, may be dipped in dilute hydrochloric acid and wiped dry with a clean rag.

The specimen is next to be held vertical and truly axial with the socket, and adjusted so that the frayed out wires lie as evenly distributed as possible within the cone-shaped cavity of the socket. A small ring of fire clay may be used at the base of the socket t vent seepage of molten metal along the rope. Commercial spelter may be used for filling the socket. It should be heated to a temperature just sufficient to give a good degree of fluidity, but must not be too hot, otherwise the wires in contact with the molten zinc have their strength impaired by the heat. This difficulty occurs more especially on small diameter specimens (one-quarter to one-half inch diameter), on account of the annealing effect on the small wires. The melted zinc should be ladled as rapidly as possible in order to ensure a uniformly cast filling for the socket.

In applying a load to the test specimen, the rate of application must be very slow during the earlier portion of the loading, thus permitting the strands and wires to bed properly upon one another.

DON'T FORCE A BELT TO RUN ON THE PULLEYS

"Many millwrights make the mistake of thinking that it is perfectly proper to force a belt to stay on its pulley by any means whatever." "They seem to think, continues a writer in "Belts," "that as long as the belt 'runs' it is all right, and is doing as much as should be expected of it. For instance, one millwright "took a piece of old three-inch rubber belt, pulled off one ply, wrapped it twice around the centre of a wooden pulley and nailed it solidly to the pulley," and then he goes on and says, "The belt immediately took its place in the centre of the pulley and stayed there."

It is true that nailing a ridge of any kind of belting on a wooden pulley to increase the crown will cause the belt to move over and run on the intensified crown, even though the alignment of the pulleys may be poor. However, such a condition is hard on the belt, as a little thought would show that if the belt has much work to do it cannot endure.

Let us say that the width of the belt is 6 inches, and that the width of the ridge nailed on the pulley is only 3 inches. 6 inches minus 3 inches equals 3 inches, which means that about 3 inches of the belt (1½ inches on each side of the centre) is not in contact with the driving pulley or driven pulley at all or is in poor contact. A very intense pressure between the belt and the pulley occurs over the 3 inches of width of the ridge. In other words, 3 inches of width of belt is compelled to do what 6 inches was intended to do.

Furthermore, with the rough face of the ridge rubbing against the equally rough face of the belt, and with the pull per square inch and the pressure per square inch doubled, it is evident that the wear on the 3-inch ridge is going to be greater than it would be on a smooth iron or smooth wooden pulley. It is quite possible that the slip is greater with the 3-inch strip than without the strip. At least the creep is as great one way as the other. From every angle, therefore, it is obvious that nailing a ridge around pulleys to increase the crown is poor engineering.

It is far better to carefully align the pulleys and shafting so that the belt will run exactly as was intended by the designers of the pulleys. By using the low crown, the entire belt surface comes in contact with the pulley, both the load and the wear are evenly distributed. In fact, pulley coverings should not be used at all. It has been proved time and again that the natural smooth face of a metal, wooden or other pulley is far superior to any roughened face. Rough faces are too hard on the belt.

The Sirocco fan, invented by Sir Samuel C. Davidson to dry tea, has since been applied for the ventilation of ships, also for forcing draught in the stokeholds. Subways and theatres also make use of it. The Sirocco fan is so made as to have a ring of blades all moving at the same velocity, thus avoiding the difficulty of the common propeller fan which has different points along the blades moving at different speeds. The part which moves is cylindrical. It takes the air at the centre and passes it through curved slats at a high degree of efficiency.

Several of Hamilton's key industries are gradually becoming busier with the result that the acuteness of the unemployment situation has been eased during the past months. During the past three weeks the International Harvester Co. has employed about another 300 of its workmen. More will be taken back as improved conditions warrant. The Canadian Westinghouse Co., has also brought in all of its employees to produce some special work.

Seven Year Review of the Furniture Industry

Manufacturers Decided to Improve Status of Industry in 1915—A Thorough Survey Was Made in 1918—A Publicity Campaign Was Started in 1920 And in Many Ways Quality of Products Has Improved

By W. CAWKELL
Secretary of Furniture Manufacturers' Association.

BEFORE REVIEWING the activities and widening scope of the Furniture Industry during recent years, I think it would be well to give the following statistical information:

	No. of Plants.	Capital.	No. Employed.	Wages.	Selling value of products.
1915	175	$18,067,929.00	7626	$3,892,994.00	$ 9,765,339.00
1919	270	24,400,099.00	9080	7,873,158.00	25,166,305.00

The imports of furniture were, 1915, $761,804.00; and for 1920, $1,825,794.00. The exports were, 1915, $307,944,00; and for 1920, $846,853.00.

The principal imports came from the United States, and the bulk of the exports were to Australia, New Zealand and Africa.

In the Autumn of 1915, furniture manufacturers met and discussed ways and means whereby they could improve the status of the industry. They decided to re-organize the Furniture Manufacturers' Association, and a strong committee was formed, who engaged a permanent secretary. Fortunately, there were within the industry, men of courage and foresight with the necessary ability to carry the organization safely through the initial stages; and eventually the association has been placed in a position where it commands the loyal co-operation of its members, the result being a robust and progressive service.

In 1918, a thorough survey was made, covering fifty of the larger Ontario furniture manufacturing concerns. These firms besides answering a questionnaire, also submitted balance sheets and trading accounts. The most striking features brought out by the compilation of these returns were (1) the large investment involved, and (2) the small return on the capital invested, which after re-adjusting the depreciation charges, showed that the profit for the year ending 1917 was only 2.6 per cent. on the capital employed, and 3.1 per cent. on the total sales. Mainly as a result of these facts, the Ontario furniture manufacturers decided to install a cost accounting department in connection with the association. This was made effective in January, 1919, and cost accounting systems have been installed in many factories, and other plants are gradually preparing for the installation; but all the furniture factories throughout the country have been made more efficient as a direct result of this work.

Another important development was the formation in 1916 of a reporting service to investigate the credit standing of any retail dealer in Canada. This reporting, or credit section had a small beginning but has now grown into a very important branch of the Association's services. This service has undoubtedly kept down losses in the furniture industry very materially, notwithstanding that the failures in all lines in Canada this year are nearly three times as numerous as they have been in previous years.

Another recent development is the labor statistical department, which keeps records of all matters in regard to labor, such as the cost of living, etc.

It is to be noted that the manufacturing of furniture is carried on largely in Ontario towns and small cities where it is the important factor in the industrial life of the community, and it is stated that a greater proportion of the artisans employed in these towns own their own homes than in other manufacturing centres, with the resulting greater happiness, prosperity and contentment.

During the Autumn of 1920, the Canadian furniture manufacturers instituted a publicity campaign, the slogan being "Better Furnished Homes Mean Greater Happiness." Under the style of the homefurnishings bureau, a newspaper advertising campaign was started, covering the whole of Canada. Full page advertisements appeared in forty-four dailies, seventy-four weeklies, and eleven farm journals, about $40,000.00 being spent in that way. It was regarded by the retail dealers as the most forward step that had ever been taken by the furniture manufacturing industry in Canada.

The work of this home furnishings bureau was continued in 1921, and another series of newspaper advertisements was inserted in the daily papers during the Autumn months. In addition to this, some of the furniture manufacturers are now advertising their particular products in newspapers and magazines, and it appears as though the manufacturing industry has definitely entered into the field of publicity advertising.

These efforts if continued will most certainly enlarge the home market for furniture. During recent years, the Canadian furniture manufacturers have greatly improved their machinery and their factory efficiency with the result that that today Canadian furniture will rank with the most artistically designed and most carefully finished furniture to be obtained anywhere.

In the higher grades of furniture, during the past seven years, there has been an increasing demand for period styles. Departing from the Colonial style, the industry has developed modern adaptations of the classic Adam, Hepplewhite, Sheraton, the Jacobean, William and Mary, Chippendale, Queen Anne, Louis XV and XVI, and some Renaissance of the Italian and Spanish schools. Walnut has been the predominating cabinet wood.

THE TEN COMMANDMENTS

"By The Boss"

RULE I. Don't lie, it wastes my time and yours. I am sure to catch you in the end, and that's the wrong end.

RULE II. Watch your work, not the clock. A long day's work makes a long day short, and a short day's work makes my face long.

RULE III. Give me more than I expect. I can afford to increase your pay if you increase my profit.

RULE IV. You owe so much to yourself that you can't afford to owe anybody else. Keep out of debt or keep out of my factory.

RULE V. Dishonesty is never an accident. Good men can see temptation when they meet it.

RULE VI. Mind your own business and in time you'll have a business of your own to mind.

RULE VII. Don't do anything which hurts your self-respect. The employee who is willing to steal for me is willing to steal from me.

RULE VIII. It's none of my business what you do at night, but if dissipation affects what you do the next day and you do half as much as I demand, you'll last half as long as you hoped.

RULE IX. Don't tell me what I'd like to hear, but what I ought to hear. I don't want a valet to my vanity, but I need one for my money.

RULE X. Don't kick if I kick. If you're worth while correcting you're worth while keeping. I don't waste time cutting specks out of rotten apples.

All bank notes issued in Canada must be secured, dollar for dollar, by gold or Dominion notes.

WHAT OUR READERS THINK AND DO

NOVEL TOOL HOLDER

By J. C. Crichton

The tool holder shown has been found to be very useful in saw mills and factories where band wheels, saw arbors, pulleys, etc., have to be turned. It really enlarges the capacity of a lathe, because you can back your saddle to its extreme, fix the tool on the post, thus allowing work of large diameter to swing successfully.

In operation, the saddle remains stationary, the tool moving instead of the saddle. We can get a travel of 1½ in. with this style of tool which is found to be ample for our purpose.

ANSWER TO THREAD CUTTING DISCUSSION

By J. Davies

In Mr. Smith's article in the December 8th issue, he says he does not understand my viewpoint. It is this, that I cannot see any reason for using a system which in some cases gives a result with a slight error, when it can be worked out correctly just as easily. Mr. Smith starts out to compare the two systems, works out an example by the system he advocates, and admits a slight error in the result. Then he commences to work the example by the other method, obtains the ratios, and then for some unaccountable reason stops at this point, and asks the question, "Where do we go from here?" instead of cancelling it down exactly as he did in his own method.

From here you simply cancel or find factors and get a correct result as follows:

$$\frac{981}{500} = \frac{109 \times 9}{50 \times 10} = \frac{109 \times 90}{50 \times 100}$$

In reference to the improbable pitch and lead screw, these were only given to show the universal application of the system propounded.

Now let us suppose we have a lead screw six threads per inch which is quite common, and it is required to cut a thread ⅜ pitch, which is also quite common. A comparison of the two methods would be as follows:—

$$\frac{375}{166} \text{ Find factors} = \frac{75 \times 5}{83 \times 2} = \frac{75 \times 50}{83 \times 20}$$

This gives a slight error in lead and requires an 83 gear which is not usually found in a set of lathe gears.

$$\frac{3}{8} \times \frac{6}{1} = \frac{18}{8} = \frac{60 \times 30}{40 \times 20}$$

This gives a correct result and a set of very common wheels.

The metric example given by Mr. Smith could be worked out as follows, and to me is preferable to the rule given by "The Machinery Handbook." It is required to cut a pitch of 3 millimeters with a lead screw six threads to the inch.

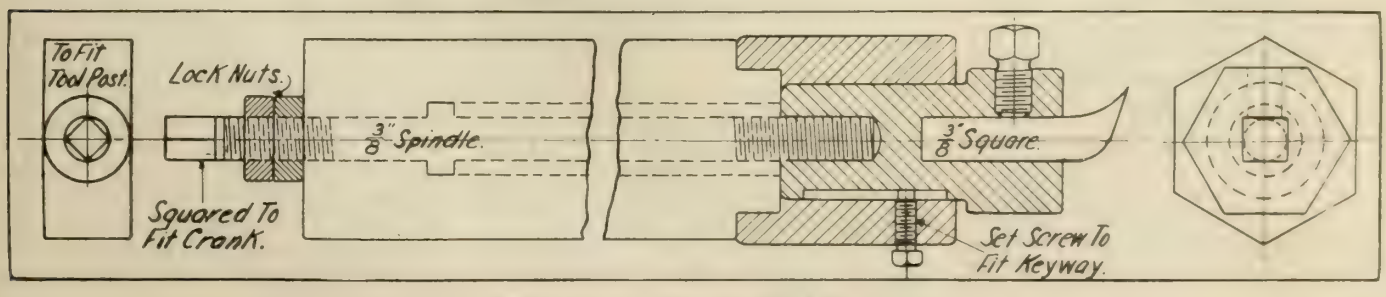
25.4 mill = 1 inch

$$1 \text{ mill} = \frac{1}{25.4} \text{ inches or } \frac{5}{127}$$

Use this as a constant and proceed as before,

$$\text{Pitch to be cut} = \frac{5}{127} \times 3 = \frac{15}{127}$$

$$\text{Ratio} = \frac{15}{127} \times \frac{6}{1} \quad \text{Gears required} = \frac{90}{127}$$



Mr. Smith says he is quite satisfied with his own system. I am also satisfied. Thus readers can choose for themselves, and we will all be satisfied.

ECONOMY IN THE BOILER-HOUSE

Below we reproduce a diagram for the guidance of boiler-house staffs, issued by the Fuel Economy Committee of the Federation of British Industries, 39 St. James's-street, London, S.W.I. The diagram can be obtained printed on metal plates 20 in. by 30 in. for hanging in the boiler-house.

1. Avoid wastage of cinders in the ashes by cleaning the fires carefully and by using suitable firebars.
2. Avoid production of black smoke and incompletely burnt gases by regularly and frequently firing coal in small quantities. Keep a proper depth of fire.
3. Regulate the draught by the damper to reduce the excess air. Try to obtain 12 per cent CO_2 in the chimney gases.
4. Keep the grate properly covered with a level fire. Use the rake when necessary for this purpose.
5. Examine the boiler setting carefully for air leakage, particularly furnace doors, cracks in the side walls, joints between the boiler shell and brickwork, and the damper slides.
6. Keep the boiler surfaces free from soot and flue dust.
7. Keep the internal boiler surfaces free from scale.
8. Do not force the boilers unnecessarily.
9. Examine the seating blocks and partition walls carefully. Repair if necessary to avoid by-passing.
10. Lag the exposed surfaces of boilers and steampipes efficiently.
11. Avoid excessive blow-down.
12. Keep the boiler filled to the working level by a continuous and steady feed.
13. Avoid leakages of steam from boiler fittings and valves.

Few people when thinking of industrial development have any idea what enormous water power is available in Canada. The recorded power available throughout the Dominion, under conditions of ordinary minimum flow and at 80 per cent efficiency is 18,255,000 horse power.

Sectional view showing the tool holder used.

Marking Country of Origin on Imported Goods

Goods Entered for Immediate Exportation or in Transit Through Canada Are Not Required to be Marked—Articles Not Susceptible of Permanent Marking May be Stamped or Labelled

FORTUNATELY, the Government substantially modified the marking act before it came into force on December 31st 1919. Several of the changes made are of considerable importance, so we reproduce this material feeling sure it will interest our readers. For convenience we shall give each item its paper section number. First comes section No.1. This new law, which applies to "all goods imported into Canada" naturally includes goods originating in the United Kingdom, British Colonies and British Possessions.

Country of Origin

2—The country of origin of a manufactured article may be the country in which the article has been finished by a substantial amount of labor amounting to not less than one-fourth the cost of production of such article in condition imported.

3—Goods entered for immediate exportation or in transit through Canada are not required to be marked.

4—When imported goods are found to be not legally marked, the appraiser will note the fact on the invoice and the additional duty shall be levied accordingly.

5—The appraiser will report all articles (and packages as hereinafter provided for) not properly marked to the collector who will notify the importer to re-deliver the unexamined packages or to arrange to mark the same and their contents under customs supervision.

6—The importer may be permitted to mark examined packages and their contents in customs warehouse, or arrange for the marking of same under customs supervision on the premises of importer.

7—Whether the marking found on goods in condition imported is as nearly indelible and permanent as the nature of the goods will permit is a question of fact to be determined in each instance by the collector, subject to the decision of the Commissioner of Customs and Excise.

8—If the importer fails to mark goods when called upon to do so by the collector, the collector may require the the same to be exported, and in default thereof, the goods shall be treated as unclaimed dating from time of importation, and if sold, must be sold on condition that they be marked by the purchaser under customs supervision.

A Substitute

9—Goods not susceptible of permanent marking may be stamped or labelled for purposes of delivery. It will be found that while certain kinds of goods as for example, chinaware and porcelain are capable of being permanently and indelibly marked in the process of manufacture, it is commercially impracticable to so mark them afterwards. Goods of this class, if not so indelibly marked in condition imported, will be subject to the additional duty as provided, but may be released upon being marked by the importer in a manner as nearly permanent or indelibly as the nature of the article will permit, as for example, by gummed labels or rubber stamp.

10—Where articles themselves incapable of being marked without injury are imported in bands, wrappers, or containers, or on cores or spools, such bands, wrappers, containers, cores or spools shall be marked so as to indicate the country of origin, unless such articles are of a class or kind not made or produced in Canada, in which case no marking is required.

Imported Containers

11—Imported containers, labels or wrappers intended to be filled with or used upon domestic products are to be marked as required by the Act, but in order to avoid the possibility of origin other than Canadian being imputed to domestc products sold in such imported containers labels or wrappers because of the marking of the latter, the words "Container," "Label" or "Wrapper," together with the indication of the country of origin as required by the regulations, shall be used. It will not constitute a non-compliance with the Act, however, so as to involve the levy of the additional duty, if the word "Container," "Label" or "Wrapper' as provided in the preceding paragraph be not used in the marking of the goods as imported, but before release from customs, this additional marking will require to be done. Provided that containers imported to be filled with Canadian produce and exported may be admitted without being marked with the country of origin, conditional on the importer certifying on the face of the entry for consumption that such containers are for use in the preparation of goods for exportation.

Section No. 12 has been cancelled.

13—The name of a manufacturer or his trade mark accompanied by the name of the country or a place in a Province, State or other division of a country where the goods have been manufactured or produced will be accepted as sufficient indication of the country of origin.

14—Fabric gloves are in the opinion of the department capable of being marked without injury either by stamping or by means of gummed labels on the inside of the wrist, where the brand or trade mark usually appears.

15—Hosiery may be so marked upon the foot where the brand or trade mark usually appears.

16—(a) Cloth and material in the web or roll shall be marked with an indication of the country of origin on the piece ticket, label or band, or on one end of each web or roll. (b) Carpets shall be marked with an indication of the country of origin by means of a protruding ticket attached to the edge of each roll at the centre. (c) Linuleums and oilcloths shall be marked with an indication of the country of origin on one end of each roll, either by stamping, stencilling or adhesive label.

Watch Dials and Movements

17—(a) With respect to watch dials and watch movements imported attached as one article, it will be deemed to be sufficient compliance with the regulations if the required indication of the country of origin appears on the movement only. (b) With respect to watches imported complete, it will be deemed to be sufficient compliance with the regulations if the movement and the case are each separately marked with the required indication of the country of origin.

The portion (c) of section 17 has also been cancelled. (d) Watches and watch movements bona fide ordered prior to October 1, 1921, may be admitted marked as formerly, without regard to this law or the regulations thereunder, provided they are imported previous to July 1, 1922.

18—The following goods will not be required to be marked with the indication of country of origin, viz:—

Goods in a crude, raw, or rough state, or goods which are not intended for sale to the consumer in the condition imported, but which are merely for use in the manufacture, construction or repair o articles in Canada. This not to apply, however, to goods elsewhere specifically provided for in these regulations. Provided that on every entry at Customs of goods as described in this Section a statement shall be placed by the importer certifying to facts sufficient to classify the importation within the provisions of this section. Section 19 has also been cancelled.

20—Goods bona fide ordered prior to the 1st October, 1921, shall not be subject to the additional duty of 10 per centum advelorem to be levied on the value for duty purposes, provided such goods are imported into Canada prior to the 1st July, 1922, but such goods shall not be released from customs possession until they have been marked, stamped, branded or labelled with an indication of the country of origin as required by the provisions of the Act, under customs supervision at the expense of the importer.

DEVELOPMENTS IN SHOP EQUIPMENT

POLISHING MACHINE

The St. Louis Machine Tool Co., St. Louis, Mo., have placed their new "Western No. 10" polishing machine on the market. The machine has a wide face pulley and long bearings for the spindle which is made from 0.40 carbon steel. The bearings have large oil reservoirs equipped with convenient methods for filling and draining. The oil in the reservoir is fed to the bearings by chains. The bases of the bearings are cast integral with the column and base. Extra point arbors are provided, either right or left hand when desired. The length of the arbor is 48 inches. Distance between wheels is 38 inches, and the centre of the arbor is 34 inches above the floor.

UTILITY FILING ATTACHMENT

A filing attachment designed to be employed with any type of drilling machine has been developed, by the Utility Tool and Mfg., Co., St. Louis, Mo. The device is suitable for either heavy duty or small work and will accommodate any shape of file and any length up to 16 inches. The table of the drilling machine may be moved to any position and the filing machine can be readily adjusted to any degree from 1 to 90. All gears are made of steel hardened and ground. In case of overstrain a small cold rolled pin in the shank becomes sheared which stops the operation of the device. This pin is easily replaced.

SELF TAPPING SCREW

A novel design of screw, which requires no tapping, is now being manufactured by the Parker Supply Co., Inc., of New York City. It will cut its own thread into die or sand-cast parts of grey iron and softer metals, without the thread on the screw being injured. The screw has a V thread of fairly coarse pitch and a cylindrical pilot which steadies the thread, while it seats itself in the metal. In using this screw, a hole is first drilled in the piece which, ordinarily, would be tapped, a few thousandths of an inch larger than the pilot, and the piece to be assembled drilled sufficiently large to provide clearance for the threads of the screw. The pilot is inserted in the hole and the screw given a few turns which drives the screw in place. The entire screw is hardened and heat treated so that the thread cuts into the metal similarly to the way of the tap.

DIE STOCK

A die-stock known as their No. 8 has recently been placed on the market by the Martin Machine Co., Inc., of Turner Falls, Mass. This stock can take round dies ranging from ⅝ inches to 2¼ inches in diameter. The loose handle of the stock may be quickly adjusted to line up with a spot hole in the side of a die by means of a sliding block, which is then held firmly in place by tightening two thumb screws. Final adjustment is made by screwing the die stock handle through the sliding block until it grips the dies snugly. The point of the die-stock that engages the spot hole of the die is made of hardened tool steel to withstand wear. The advantage of this tool is the possibility of using one stock for dies of various diameters. It is intended for use by machinists, garage men and plumbers.

INCLINABLE PRESSES

Two recent additions to the line of inclinable presses built by the Loshbough-Jordan Tool & Machine Co., of Elkhart, Ind., are known to the trade as their No. 5-Special and their No. O. The No. 5-Special is exactly the same as their No. 5 except that the die space is 12 inches whereas on the regular machine it is only 7 inches.

The No. O press is similar in design to the standard presses of the inclinable type built by this concern, but it is of smaller dimensions. The opening in the bed is 3 by 5 inches; opening through back 5½ inches; depth of throat 3½ inches; adjustment of stroke 4½ inches; standard stroke 1 inch. The pressure exerted by the slide is between 5 and 7 tons. One half horse power is required. The weight is 300 lbs. and with floor stand 400 lbs.

ELECTRIC GRINDING MACHINE

A two horse power electric grinding machine has recently been placed on the market by the Louisville Electric Manufacturing Co., Louisville, Ky. It has improved ventilation with an air intake so located that clean air is drawn through the motor. The machine will operate continuously without exceeding temperature limits and for intermittent duty will operate with air intake closed. Ball bearings are provided in dust proof housings. The safety hoods are of steel and have hinged side walls to enable wheels to be replaced. The rests are fully adjustable. The motor-starting switch is enclosed in the column. The water pot is attached to the column. Direct or alternating current can be used to drive the motor. The centre line of the grinding arm is 38 inches above the floor. The wheels used are 12 inches diameter, 2 in. face by 1 in. hole. The approximate weight of the machine is 400 lbs.

AUTOMATIC AIR COMPRESSOR

A full automatic air compressor has been placed on the market by the Hobart Bros. Co., of Troy, Ohio. After being once installed, the makers claim that it will keep air in the tank at a constant pressure with no attention whatever. The compressor unit is electrically driven from an ordinary lighting circuit, and is mounted on top of the supply tank. The compressor is of the rotary type directly connected to the motor. Ball bearings insure quiet running. A magnetic pressure release is used which enables the motor to start without load, and is thus economical in its consumption of electricity.

PORTABLE ELECTRIC WELDING BELT-DRIVEN AIR COMPRESSORS

The Ingersoll-Rand Company, New York, has announced a new line of belt-driven air compressors known as the "Imperial" Type XCB. This line of compressors is provided with Ingersoll-Rand plate valves for both the air intake and discharge, and a five step clearance control for the output of the compressor. The plate valves are kept in alignment throughout their operation without wearing guides. The clearance control, so successful on larger, electric-driven, types of compressors has been used. This control provides a method of securing efficient operation at partial loads, as it automatically loads or unloads the compressor in five successive steps as governed by the reduction or addition of clearance space in the air cylinders which has a direct relation to the amount of air taken in and compressed. The compressor will operate at full three quarter, one half, one quarter, and no load. At any one step the reduction of input required is in proportion to the reduction in the output capacity.

The compressors can be furnished in a single stage style for low pressures and in the two stage design for higher pressures. On the two stage machine

clearance space in the proper proportion is added simultaneously for both the high and low pressure cylinders, thus giving a constant rate of compression. A special feautre in the control is the provision of a stop which will prevent the compressor being operated at an overload. The piston displacement for the 100 pound discharge pressure ranges from 610 to 1505 cubic feet of free air per minute. A short driving belt with a floating idler can be furnished for driving the compressor. This method of drive saves floor space and gives a larger arc of contact for the belt.

SEMI-AUTOMATIC ARC-WELDING TOOL

A semi automatic arc-welding tool has just been placed on the market by the General Electric Co., of Shenectady, N. Y. It is designed to be of use in conjunction with the full automatic arc-welding head which was brought out some time ago by this firm. The new device enables the operator to direct the arc as required by irregular conditions in the work to be welded. The tool is held by the operator and acts as a guide to the electrode wire. The handle of the tool resembles that of an automatic pistol. This handle controls the switch for operating the control on the panel of the automatic welder, to stop and start the electrode wire movements.

The tool has attached to it a 10-foot length of flexible steel tubing which is fitted with an adapter on the other end for attachment to the automatic welding head. The electrode wire passes from the feed rolls into the flexible tubing and thence to the arc through a guide nozzle in the welding tool. With the new device the automatic welder functions as usual, tending to hold the arc length constant, but the operator directs the arc as required by the particular job in hand.

The real field of operation for this tool is work in which the seams to be welded are of irregular contour, or large work where the travel mechanism and clamping operations of the full automatic welder would be complicated. In many instances seams are not accurately prepared, so that there are gaps in some places and tight fits in others. It is rather difficult to compensate for these conditions by varying the speed, or by manipulation of the electrode in the full automatic welder, but with the semi-automatic arrangement these conditions can be taken care of.

GRINDING SPINDLES

A line of grinding spindles has recently been designed and placed on the market by the Coates Machine Tool Co. Inc., of New York City. These grinding spindles are known by the trade name of "Fortuna". This line of grinding spindles consists of three spindles, the first being intended for internal grinding, second for both face and internal grinding and the third for vertical internal and face grinding. The spindles may be driven either from a pulley or by a motor. A clamp block is provided on which is mounted the motor or pulley as well as the spindle itself. This clamping block may be attached to the slide of a machine and the feeding of the grinding wheel across the work may be accomplished in much the same manner as other tools are fed. This particular line of clamp block provided with these spindles is most applicable to a lathe. "Norma" ball bearings are provided in all cases in the spindles. One advantage of the clamping block is that it permits a quick reversing of the counter shaft, or the motor, which will permit of work being revolved to the left as readily as to the right. The construction of the attachments permits grinding wheels to be run at a maximum speed.

UNIVERSAL JOINT

A universal joint, said to be quite apart from the conventional designs, has recently been designed and is now being marketed by the Borgeson Manufacturing Co., Torrington, Conn. The yoked ends are milled from solid cold-rolled steel bars. The parts subject to motion and wear are of mild steel carbonized and hardened. The design is of the "ball" type, but the ball is a cube, with corners rounded and of the "split" design, the two halves being held together with a bolt. The nut on this bolt is secured by a cotter pin. Taper pins, upon which the ball swivels, are driven into the wings of the sockets, or yoke pieces, and are staked in place. The pins are provided with shoulders to insure against the possibility or working loose. After continued use, if wear occurs, it can be eliminated by removing the ball, then withdrawing the bolt, and on a disk grinder slightly touching up the two parts. On account of the tapered bearing of the pins it will be found that after this operation the joints will be tight when re-assembled.

BALL-BEARING BUFFING MACHINE

The J. G. Blount Co., Everett, Mass., has just brought out a line of buffing machines which are marketed in three sizes. The design of these machines is very similar to the regular line of machines manufactured by this concern except that the new machines are equipped with S K F ball bearings. The bearings are all mounted in dust proof housings. The spindles are of high carbon steel carefully ground to size, and well balanced. A taper point is fitted to the right hand end of the spindles to accommodate small wheels. The contact surfaces throughout the machines are all machined insuring rigidity. The machines can be supplied with the head only for mounting on a bench or they can be equipped with a pedestal. Two types of countershaft are available, the shelf oiling type or the Hyatt Roller bearing type.

INDICATING CALIPER

The F. W. Horstman Co., of Irvington, N. J. have recently placed on the market an extension-beam indicating caliper, which is a modification of the indicating caliper placed on the market several years ago by this firm. The beam is ½ inch in diameter and can be supplied in any length desired. To the beam is attached two arms by means of split clamps. One of these arms houses an indicator and the other arm houses an adjustment screw. The rear surfaces on the arms are machined flat so that the instrument may be used while lying on a flat surface in a horizontal plane. The principal use of the device is for ascertaining the exact amount that work varies from a desired standard. It is set by placing a piece of the desired length between the plunger of the indicator and the adjusting screw. The adjusting screw is then adjusted until the pointer of the indicator registers zero. Then by applying the instrument to various examples of the work variations in the length of the pieces from that of the gauge or master piece can be observed by noting the amount that the indicator pointer moves from the zero mark. Internal distances above a certain minimum limit can be measured in much the same way as just explained. All that is necessary is to reverse the arms on the beam. Two classes of work for which the instrument is especially valuable are the gaging across the face of large diameter work in a lathe, or across wide pieces being machined on a planer.

VISES AND BAR CLAMPS

The Rae Machine Tool Works, Hamilton, Ont., have marketed a new line of vises and clamp bars. This covers wood-workers' vises—amateur and household type, machinist vises with stationary and swivel base, oval slide vises, and self locking pipe vises. Then they have several sizes of bar clamps, and they claim that only the best material goes into their product. The parts of the pipe vises and bar clamps are made of malleable iron, and in the latter case all parts are interchangeable.

PORTABLE ELECTRIC GRINDING MACHINE

A portable electric grinding machine intended for use on any type of machine tool or in a vise for the accurate grinding of hardened parts has been developed by Arva Stroud of New York City. The machine is furnished in two models which are driven by ½ and 1-horsepower motors, respectively. The motors are of the universal commutator type operating on alternating or direct current. Grinding wheels 5 inches in diameter are supplied. The net weight of the complete machine is about 22 pounds.

Keep Up On The Highlands

CUSTOM, bearded and patriarchal, has for generations flattered itself with customs old and mellow. Easter, for instance, never comes without dumping a lap full of wonderful millinery creations down on the heads of ladies. Thanksgiving regales us with the lordly turkey, with tender viands and cranberry sauce. Christmas brings forth jolly Santa Claus, who for centuries has been dispensing the same infatuating laughter and generosity.

So, too, the New Year, hopeful and optimistic as a morning in April, invites everyone to make a resolution,—any one of a thousand and three will do so long as it is sufficiently brittle to be broken when expediency demands! If any one feels so inspired that he wants to start January with a pocket stuffed, they will all be accounted to the resolutioner for good and marked up to his credit on the score board of time. But for most ordinary types of bipeds one good intention, molded into a fair, round, innocent shape, like a rosy-hued apple, is about all that experience shows is wise to undertake. Even this one should be selected and nurtured with affectionate care or before a month has passed it will have been disfigured and abandoned.

The ability to make resolutions is not of a high character. Any babbling tongue can order up a few words, saddled and bridled, like a trooper his horse, ready to journey forth with the same lofty spirit as a knight in quest of the Holy Grail but few persons have the strength of mind or the sincerity of motive to pursue a worthy determination to its day of achievement. It is easy to start out on the upland road, girded and mantled with white robes, face elevated and eyes forward, typifying the courageous and noble, but in too many ninety-nines out of every hundred the weary feet soon descend to lower levels. The resolution baggage taken on January 1st is thrown off bit by bit, till when February 1st comes, the highway is strewn with broken pledges.

To the readers of Canadian Machinery we give a word of cheer. Let the New Year be introduced with joviality and glee, let him drink out of the cup of mirth, let him plume his feathers before the mirror of optimism, but when the day is gone and the halls are silent again, let the inspiration of the Great Day leave behind it a permanent record—that of one resolution MADE and KEPT. The mistakes, errors and experiences of yesterday should be steps up to a better tomorrow.

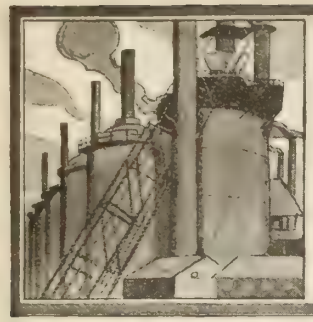
In the coming months metal workers may well cast the flaws aside and work with purposes that ring as clear as high grade steel. But whatever the resolution may be with which one starts out, whether moral, mental or commercial, let it be maintained throughout the future, as a friend of youth is often held through life.

Success In Salesmanship

ON ANOTHER page of this issue appears an article on "The Selection and Training of Salesmen." This is a very important subject, and manufacturers and executives should read this material carefully as it contains many suggestions of value. We are now in a period when salesmen have an opportunity to prove whether they are order takers or order getters. Success in salesmanship depends on many things. A good appearance; an optimistic outlook; a convincing manner; all these are necessary, but such factors alone cannot make success. They merely help.

One of the primary essentials of a successful salesman is a thorough knowledge of the goods he is selling. Many a prospect has been lost through lack of confidence. This condition is created by the salesman himself when he displays an ignorance of the manufacturing process of his line. Before a traveller goes on the road he should spend some time in the factory, become acquainted with the process of manufacture, quality of raw materials, and any other points which will help his selling talk.

After he secures his shop experience, he must develop the faculty of saying the right thing at the right time; he should be able to sense instinctively the degree of response he is obtaining, and above all he must be patient



There is also the point where silence is golden. It is not always the glib talker that makes the greatest impression. A man of few words, yet who speaks those few with authority, can create more confidence than a salesman who talks voluminously, but vacantly.

Unfortunately some travellers have not grasped the true meaning of the expression "Good appearance."

They may be neat, but their idea of good dress is loud checks, brilliant ties, spats, etc. Such a salesman often wonders why he doesn't land the business, but if he could only read the minds of his prospective customers, he would soon tone down his clothes which fairly hurt the optic gaze.

Last, but most important of all, comes "Health." A salesman who takes care of himself while on the road has 50 per cent. of his battle won. He can get up in the morning clear of eye and mind, and has the advantage over his competitors who feel that a nice quiet (?) game of poker is the end and beginning of a perfect day.

Manufacturers have come to the point where they must get orders. If their present staff cannot land the business it is only reasonable to expect that they will secure help that will produce results. The year 1922 is a brand NEW year, and it will be what we make it. The three I's will carry you far; Initiative; Industry; Intrepidity. Use them, they are valuable helps.

MARKET DEVELOPMENTS

All Markets Reflect the Holiday Season

Pittsburgh Reports a Quiet Finished Steel and Pig Iron Market—Coke is Selling at Low Prices—Montreal Feels Confident About the Future—Toronto Activities Are Very Light

THE HOLIDAY season is making itself felt on all markets. Pittsburgh says that both finished steel and pig iron lines are very quiet. There has been no change in prices since December 22nd, when wire products took a drop. However, even this reduction did not represent corresponding declines on the open market, as the cause of the reduction was really the cutting of nominal prices by the independents. Since the corporation announced its new prices, the markets have been steady, no fresh price cutting having occurred.

Speaking on the future of steel prices, Pittsburgh says that the iron and steel producing trade has passed into a period of close competition. This is expected to continue for several years, so that we can look for a "buyer's," rather than a "seller's" market.

Prices have been made on furnace coke during the past two weeks that were not considered possible six weeks ago. Some contracts for this material have been made at $3.10, and even lower prices than this are spoken of.

Montreal reports a very quiet market in all lines. In spite of the lull, optimism prevails, and good things are looked for in 1922. Present building plans are rosy. Canadian railways have not yet placed their orders, and other local firms are expecting business in the near future.

Toronto comes forward this week feeling better, although not much business is actually being closed. The betterment is in feeling only, but travellers bring back the cheering report that all through the country things are picking up. They say that manufacturers have decided to forget the old year and get out and obtain results in the new. The small tool market has picked up a little and feels confident about the future.

VARIOUS LINES ARE VERY QUIET EXPECT BUYERS' MARKET FOR SOME TIME

PITTSBURGH, January 2.—The finished steel markets have been altogether inactive in the past week, thus being true to all the precedents. The influence is not so much the holidays, as the annual inventory.

As is to be expected in a quiet market, there have been no price developments. The last important changes in prices were in connection with the reductions the Steel Corporation made, December 15 on tubular goods, and December 22 on wire products. These reductions did not represent corresponding declines in the open market, as the market had declined more or less by way of independents cutting the nominal prices. Since the corporation put out its new prices the markets on these lines have been very steady, the independents not having started any fresh price cutting. Quite possibly they will not do any cutting in the near future, as the new prices are very low, relative to cost of production.

Finished Steel Market

The finished steel market having stood still long enough to be counted, following may be regarded as regular market prices: Bars, shapes and plates, 1.50c.; hoops, bands and hot rolled strips, 2.00c.; plain wire, 2.25c.; galvanized wire, 2.75c.; wire nails, $2.50; standard steel pipe, 71 per cent. basing discount; blue annealed sheets, 2.25c.; black sheets, 3.00c.; galvanized sheets, 4.00c.; tin plate, $4.75.

Varying degrees of firmness are exhibited by the different markets. Bars, shapes and plates sometimes bring a little over 1.50c., particularly in carloads, while on a distinctly large lot 1.50c. might be shaded. Strips would probably be shaded on a large lot, but the test does not come as orders are in very small lots. Wire products are very firm, and this seems to be the case with pipe. The blue annealed sheet quotation of 2.25c. is probably firm with the jobbing mills, while the heavier gauges would be sold by plate mills at a lower price. Black and galvanized sheets are phenomenally rigid at 3.00c. and 4.00c. respectively. Tin plate is quite steady, but of course some large buyers can secure slight concessions, this having been the usual thing in the tin plate market.

Future of Prices

As to the future of steel prices, it is very easy to argue that prices will have to be higher, and therefore very many do so. Present prices are at around the cost of production, and some say they are below the cost of production. One is not observant, however, if he does not see that the whole iron and steel producing trade has passed into a period, probably of several years' duration, in which there will be close competition and not enough demand to take care of all the productive capacity. This does not mean that demand will not be fairly large or that the country will not be busy, the point being simply that the producing capacity has grown disproportionately. For the country to give work to the entire iron and steel producing capacity it would have to curtail many of its other activities and take to consuming iron and steel instead, or would have to find many new ways in which to use iron and steel.

That is, demand can be large from the viewpoint of buyers and still be small from the viewpoint of sellers, therefore there will probably be a "buyers' market" for several years, and it will not be easy to get the price of any commodity up, once it has gone down. Quite possibly there will be a number of paper advances, by the mills filling up for a few months at strenuously competitive prices and then advancing their asking prices until the orders are worked off. That is a very old practice, and even in the past few months it has been seen in some commodities, particularly sheets. Somewhat the same thing was

attempted in hoops two or three months ago, sales being made at around 2.00c., the mills afterwards all advancing to 2.25c., but in a short time they began selling at 2.00c. again.

Coke Deve'opments

A little suggestion as to the general situation is furnished by recent doings in the coke market. Prices have been made on furnace coke in the past fortnight, for the first quarter or first half of 1922, that were not considered a possibility six weeks ago. At that time spot furheld then that this was a temporary Connellsville ovens, with no takers except for occasional odd lots for use outside blast furnace industry. It was held then that this was a temporary weakness and that of course coke would bring close to $3.50 for first quarter. The basic idea then was that while there was strenuous competition at the time the competition would not be so keen after the holidays.

The outcome has been different. While it is claimed that some first quarter contracts were made recently at $3.25, $3.40 and 3:50, it is now known that a contract has been made at $3.10, and even that is not all. A Youngstown steel interest, which has a by-product coking plant with a capacity slightly under the requirements of all its blast furnaces when running full, has been supplying three outside furnaces with coke, as its own requirements were light. A few weeks ago it looked as if this interest would refuse to continue the supply after January 1, but lately it opened negotiations again, evidently concluding its own requirements would be relatively light. One of the contracts went back to Connellsville coke and now it is learned that a new furnace has been taken on, not simply for the first quarter, but through the first half, and it is reported on what seems to be excellent authority that the price in this case was only $2.90, Connellsville basis.

Such developments seem to suggest that when men get down to actual trading very close prices have to be made, and when that is the case in coke there is no reason to suppose it will not be the case in pig iron and in steel products generally. In the past six years the seller has had the upper hand. In the next few years the buyer will have the upper hand. Why not?

The Pittsburgh-valley pig iron market has continued very quiet. It seems that in the past two or three weeks eastern Pennsylvania furnaces have been making a drive for business, at the expense of prices, because they did not want to blow out or to pile iron, and a fair sized tonnage has been sold, at prices the consumers could not resist. Somewhat the same thing has occurred in southern iron, but in that case it seems there were stocks of iron to be sold. Nothing of the sort has been attempted in the local market, and nothing is likely to be. The western Pennsylvania and valley furnaces are in the habit of sitting tight and waiting for inquiries to develop before they compete.

Bessemer remains quotable at $20, valley, and foundry at $19.50. Basic iron is now fairly quotable at $18.25, valley. The market price for some time was $19, and recently a steel works interest made one sale at $18.25. The merchant furnaces have accepted this as a governing sale and now quote $18.25 as their price. There have been no sales of any grade of importance in the past week.

POINTS IN WEEK'S MARKETING NOTES

Prices of steel in a semi-finished condition such as sheets, plates, bars, rails, and structural shapes, remain unchanged on the Montreal market. Quotations are low, and the stocks in the warehouses of the various jobbers are also low.

Canadian Railways have still to come into the market for their 1922 requirements. This business is looked for in the near future, and present building plans in the Montreal district makes it appear as if there will be a good demand for structural steel when spring opens up.

The standardization idea is being adopted by Canadian Railways. This will mean better purchases than if a varying and conglomerate range of equipment is carried. The pig iron market in Montreal is very quiet.

The Toronto small tool market shows a more optimistic spirit. Dealers feel that good things are in store, and that 1922 will see many improvements in their own particular market. The machine tool business is very quiet, but even here we find a note of optimism.

The metal market locally is quiet but steady. Dealers expect a gradual improvement from now on, and as stocks in scrap are said to be quite low in the foundries, business will pick up considerably when plants extend their activities.

The Pittsburgh-Valley pig iron market remains very quiet. Some furnaces have been making a drive for business, at the expense of prices, but locally, Pittsburgh reports no such move, with little likelihood of it occurring.

The finished steel markets have been quiet in the Pittsburgh district, no changes in price developing. The iron and steel producing trade will encounter keen competition for some time to come. It is quite likely that this will be a buyers' market for several years, thus it will be no easy matter to increase prices once they have been lowered.

MORE OPTIMISTIC SPIRIT ON MARKET

TORONTO, January 2.—Now that old Father Time has swung his scythe on another year, dealers, and those interested in market conditions locally, have decided to forget there was such a period as 1921. In one way it is just as well to forget the year just closed, for it was by no means a good one for the iron and steel industry. With the start of the New Year, everyone seems to be taking a more optimistic view. Not that they expect an immediate or sensational change for the better, but simply that they feel the worst is over. From now on a steady improvement can be looked for in all lines, although the steel market will not likely show any upward trend until the end of February or the beginning of March. In fact a slight drop in production can be looked for this month as various of the mills have given their workers a holiday over the New Year.

Conditions During the Week

The closing week in December fulfilled our recent prophecy, viz, that steel dealers would experience a much better month in December than in November. One dealer claims that his sales during December were far ahead of his expectations. In fact he never remembers a December in his experience which showed such good results. This business was all the more welcome, because it was unexpected. Low stocks seem to be the only answer for the unlooked for demand, and if this is the correct answer, and it seems the only feasible one, augurs well for business in the spring when things open up.

As far as prices are concerned there are no changes. Quotations remain firm, and as the reductions which occurred in boiler tubes last week are now history, we need not refer to this phase in the market.

Small Tools

A very decided tone of optimism exists on the small tool market. Dealers, in travelling over the country, have found manufacturers very cheerful. "Every one I spoke to last week had a cheering story to tell," commented one dealer to Canadian Machinery. Manufacturers generally feel that February will see a change, according to this dealer, and that business from then on is going to be very satisfactory.

Lumbermen report better conditions, this in turn meaning business for the small tool dealer handling wood working lines.

Machine Tool Market

Unfortunately we cannot report any improvement in the machine tool market. Dealers frankly admit that they do not expect any demand for some time to come. They are hoping when things open up in the spring that manufacturers will scrap some of their obsolete but runnable machinery, replacing this equipment with production ma-

chines. Competition is bound to be keen for some time to come, so that plant owners will have to be on their toes to produce at lowest cost. This is the comforting thought which keeps hope alive in machine tool dealers' breasts. In the meantime every nook and cranny is being scoured carefully for possible business, dealers refusing to let the grass grow under their feet.

Scrap Metal Market

"No change, but a better outlook," is the way one dealer summed up the metal situation this week. He went on to say he expected a steady but gradual improvement from now on. As soon as foundries open up watch the scrap market stiffen. Stocks are very low in plant yards, and once let foundry owners, get a whiff of possible business, then watch the orders start to roll in. Taken all in all, the week can be said to be the period when optimism took a new hold on life and that 1922 received an encouraging start so far as the Iron and Steel market is concerned.

RAILWAYS ARE COMING TO STANDARDS GOOD BUSINESS LOOKED FOR SHORTLY

MONTREAL, January 4th:—Illustrating the old proverb that "Hope springs eternal in the human breast," the entry into the year 1922 brings forth that optimistic spirit in a fuller measure, than is usual in normal years. The strenuous times that have been experienced during the last year are matters of the past. Experiences gained will be used to good advantage in the coming year. The metal working industries are acknowledged to be among the basic or key industries, yet, in the general improvement of trade, that we so confidently look forward to, it is hardly expected that these industries will be the prime mover in such an improvement. The expansion and development of our iron and steel business from the mining of the ore to the finished article, during the war years extended to a point far beyond that which is justified by our peace time needs. For that reason, men were attracted from other lines of endeavor to this branch of labor. Thus, the great abundance of manufacturing plants are only operating on very short time causing a great deal of unemployment. Generally quiet conditions create only a comparatively small demand for material, from our railways and our large industrial centres. During the year 1921 vast sums representing idle machinery, stocks, and superfluous equipment and supplies, were written off. Staffs were reduced to a minimum, dead wood was eliminated, re-organization to a greater or less degree was completed, and coincident with these changes some say that the bottom has been reached in the way of prices. With the old burdens cast aside, and with the mist which surrounded the future, to a great extent, removed, manufacturers are ready to start 1922 with courage, and with hope, that will be backed with an organized and well directed effort that will not countenance failure.

Prices in Steel

Prices of steel in a semi-finished condition such as sheets, plates bars, rails and structural shapes remain unchanged. The quotations are very low indeed. When the base price of steel drops below three cents it is always a good time to buy. Stocks in the warehouses of the jobber, as well as in the shops, are very low in all lines. Shortly, certain general plans for 1922 will develop, for these matters will demand attention in the coming year. Then too each year brings forth its quota of regular jobs. This, together with many new business ventures, will present a volume of business which represents a definite consumption of steel products. Thus, between the present time and the first of April there will be orders for stock and for contracts from jobbers and manufacturers. The rail mills and steel plants have had a reasonably good year all things being considered. In fact, the Algoma Steel Company's mills at the Canadian Sault have been operating at a greater percentage of their capacity, throughout the year, than has any other steel plant in Canada or the United States.

The Canadian Railways have not come into the market as yet for their requirements for the year. Plans for building are being made on a large scale locally, and throughout the province. This will call for a large volume of structural steel. The demand for sheets and plates has been reasonably large all through the closing months and from the manufacturing schedules now being announced the demand will continue. The Parker Motor Car Co., with head offices in this city claim to have closed contracts for thirty-five hundred cars. They plan to assemble these machines in their own factory locally. Several large hydro-electric power developments are contemplated. If the contract for the turbines and other equipment required for the Winnipeg development is placed in Canada, there is an indication that the work will be placed with a local firm, the Dominion Engineering Works, Ltd. In the Maritime Provinces several other developments are receiving close consideration.

The Canadian Railways are developing the idea of standardization as far as possible. It is stated that trucks will be reduced to a minimum number as will all other major assembled units. The smaller articles have been standardized for some time past. The Canadian Pacific claim they will soon have their types of locomotives reduced to about six—namely, light and heavy passenger; light and heavy freight, and light and heavy switching. Of course, this is a theoretical idea and can never be really attained due to constantly increasing improvements and developments in locomotive design. With a railway well standardized, it makes for greater purchases, however, while with a varying and conglomerate range of equipment it would be impossible to carry stores on a scale that would be necessary, as the investment would be too great. The result would be that the stores would not receive proper attention; inventories would be hard to make, and the stores department would become an unsatisfactory unit. On the other hand with a well regulated and standardized system, large and profitable orders would be received at regular intervals by jobbers and manufacturers. There is no doubt but that the steel situation will gradually improve and with the advent of spring will have attained very satisfactory dimensions.

Pig Iron Market

The pig iron market is very quiet this week. Some time ago it was evident that most foundries had a sufficient supply of pig in their yards for the modest requirements for the balance of the year. In fact most foundries are not operating this week, even their office staffs being somewhat disorganized. To further add to the general dullness it was decided some two weeks ago not to change any prices or quotations until after the New Year. Thus there was no possible advantage to be gained by manufacturers in placing orders for pig iron before the early part of January, unless same was required for use before that time. Therefore, for the last week there has hardly been any tonnage moving. There is some speculation in connection with the price to be quoted for January delivery. The producers claim the price is firm and is quite likely to be advanced as business increases. On the other hand the shops seem to be of the opinion that a further drop can be expected.

Machine tool sales have again been conspicuous by their absence this week. This condition, of course, is only to be expected at this season of the year. Bulletins from the manufacturers of tools describe some really very efficient machines with many real labor saving devices. Prices generally are coming down and there is every probability of a gradual improvement.

Small Tools and Supplies

Small tools and supplies have had a quiet week, but with the opening of the shops next week business will undoubtedly improve. Prices are pretty fairly firm all along the line, and prospects for the New Year are good.

The non-ferrous metals have been quiet, in sympathy with the rest of the metal working trading. The rise in value of the Canadian dollar in New York will, of course, have a reaction in the translation of New York quotations, having a tendency to slightly lower quotations, which is entirely foreign to the factors which usually influence these

(Continued on page 48)

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

The city council of Montreal, Quebec, plan waterworks improvement for the coming year to the extent of $700,000.

A mill-work contract for a car cleaning shop costing $50,000 in the Glen Yards for the C. P. R. in Montreal, Quebec, has been granted.

Contracts for the erection of a high school in North Toronto, Ontario, costing $160,000 have been granted.

Additional contracts for a school costing $100,000 for Verdun, Quebec, have been granted.

A steel contract has been awarded to erect a factory for the Universal Cement Casket Co., Dunnville, Ont.

Plumbing and heating contracts for additions to hospital costing $107,986 for the Royal Jubilee hospital, Victoria, B. C., have been awarded.

The general contracts for the erection of a Technical school costing $450,000 for Windsor and Walkerville School Board at Windsor, Ont., have been awarded.

Additional contracts for alterations to the office building costing $150,000 for the Toronto Hydro Electric and Toronto Transportation Commission have been awarded.

Contracts for re-inforced concrete for addition to factory costing $75,000 for George Weston Ltd., 134 Peter Street, Toronto, have been granted.

Contracts for addition to the office building costing $35,000 for Merchants Fire Insurance Co., 86 Adelaide St., W., Toronto, have been awarded.

Electrical contracts for a market building costing $150,000 at Windsor, Ontario, have been awarded.

Mr. J. D. Johnston, architect, Kentville, N. S., is preparing plans for a telephone exchange for the Maritime Telegraph and Telephone Co., Hollis St., Halifax, N. S.

Canadian trade statistics show an increase in total exports to Italy of $22,900,000 for the past twelve months, exports having risen from $24,300,000 August-September, 1920, to $47,200,000 August-September, 1921.

Speaking on business conditions in the Argentine, Trade Commissioner B. S. Webb says that import and export trade has been in a state of partial paralysis during the past few months, but there is every reason to believe that the worst is now passed and that commercial conditions from now on will steadily improve.

The T. G. Rice Wire Mfg. Co., 134 King St. W., Toronto, has recently been incorporated under the name of Rice Wire and Metal Goods, Ltd.

The Increase in production of coal in the Province of Alberta is equivalent to the addition of one new colliery of one thousand tons per day output, each year for the last eighteen years.

There have been more garages built in Toronto, Ontario, than houses in the year, 1921. According to figures received from the City Architect department, 3,078 garages have been built during the current year.

At the annual meeting of the Oak Tire & Rubber Company approval was given the plans for enlarging the present factory, which has been made necessary by the increased demand. It was stated at the meeting that every indication pointed to a banner year in 1922.

Wall Street interests are said to have their eyes on Northern Ontario. $25,000,000 ready money is waiting investment and will become available as soon as the financial interests are assured that the Ontario government will cooperate by placing water power for development purposes at the disposal of the financiers.

Contracts for the last two sections of road on the main highway between Fredericton and Woodstock, N. B., have been let to Concrete Builders, Ltd., Fredericton, and Guildford & Hammond of Dumfries. The two contracts are for about 13 miles of road, which will practically complete the Fredericton-Woodstock highway with the exception of a short section at Meductic which will be under the supervision of the highway department. This highway, when completed, will have cost about $500,000.

In the December 8th issue of Canadian Machinery we mentioned that the Wm. Hamilton Co., Peterborough, Ont., were building certain machines for the Canadian General Electric Co., which is establishing a plant at St. Catharines. This information was rather misleading for what they are actually supplying are the hydraulic turbines for the new power plant of the Canadian General Electric Co., at Nassau, Ont. This company has also told us they are supplying full equipment for the power plant of the new Red Arrow Tire Co. plant at Peterborough, Ont.

The attention of Canadian exporters is directed to the new service which is being maintained by the Canadian Pacific Steamships, Ltd., from St. John to Havana, Cuba. This service was inaugurated by the ss. Sicilian on December 5, and is to be a regular passenger and freight service between Canada and Cuba, with Boston as a port of call on each trip.

Major H. A. Chisholm, late Canadian Government Trade Commissioner in Havana, Cuba, sailed on the 24th December to open the new office of the Commercial Intelligence Service in Calcutta. It is expected that Major Chisholm will arrive at Calcutta a little before the end of January. Until offices have been engaged in Calcutta, correspondence should be addressed care of H. M. Trade Commissioner, P. O. Box 683, Calcutta.

The largest Hydro Electric Plant at Chippawa was officially opened on Wednesday, December 28th. About 2,000 municipal representatives were present, and water was released into the first installed turbine setting in motion the 55,000 H. P. generator. At the present time only one turbine will be used but when the actual plant is completed there will be nine turbines in all which will have approximately a capacity of 650,000 H. P.

A firm of rubber manufacturers is laying an experimental section or road with rubber blocks. This is to be tried as a substitute, in fact an improvement over the present wood paved streets of Melbourne. The rubber blocks used, have an ebonite base, reinforced with expanded metal, and are fixed on to a concrete foundation to which they are held by screws. It is considered that only the present low price of rubber warrants its use for road purposes, and that competition with hardwood blocks, which have proven very satisfactory, is unlikely to any large extent.

A new concern, Hadfields (Australia) Ltd., has been formed and registered with a capital of £500,000 to take over the works of the Australian Electrical Steel, Ltd. at Alexandria, and a plant, which is now in the course of erection, at Perth, Western Australia. The Australian Electrical Steel, which will be absorbed by the new company, was the pioneer in Australia in the manufacture of steel by the electrical process. It is stated that the new company expects to so expand the scope of its manufacture that all of the high-grade steel now imported from overseas will in future be made in Australia.

Mr. J. D. Best, Glencoe, Ontario is in the market for equipment for drilling oil wells.

Gropp Bros., Penetang, Ontario, are in the market for saw-mill machinery, boiler engine, belting, etc.

Mr. W. W. Avey, Norwich, Ontario, is in the market for engine, boiler and complete equipment for new planing mill.

The Taylor and Arnold Engineering Co., have been appointed to act as dealers for the Davis-Bournonville Co., in Ontario, Quebec, New Brunswick, Nova Scotia and Newfoundland.

The "Weekly Bulletin," the publication of the dept. of trade and commerce, will change the name of their booklet, to "Commercial Intelligence Journal," as they feel the new title will be more descriptive of their efforts.

The total value of buildings erected at Timmins, Ontario, this year is estimated at $100,000. Within the limits of the town of Timmins there were permits taken out for the erection of 216 buildings, the total value of which is estimated at $207,353.

The secretary of the Building Trade Union has stated that the unemployment situation at the present time is more hopeful than at this time last year. He says there is work in sight which, with government work, will reduce unemployment in the building trades industry to a minimum this winter.

Many friends will be sorry to learn of the death of Mr. John J. Cunningham, president and general manager of the Western Foundry Co., Wingham, Ont. He died in Toronto on Tuesday, December 27th. The deceased was well known in Western Ontario and had been prominent in the manufacture of stoves for a number of years.

James Whalen, president of the Port Arthur Shipbuilding Co., has announced that they have received a contract from the Matthews Steamship Co., Toronto, for the construction of a 550 foot lake freighter. The erection of this will take place in Toronto. Construction will give employment to 700 men well into next summer. A later report states that 400 additional men will be taken on the payroll to work on a contract for paper machinery required by the Provincial Paper mills, this work requiring two years to complete.

United States exports to Canada declined by $3,606,000 in November as compared with the previous month, according to an official summary of the month's trade issued by the Department of Commerce. Goods were sold the Dominion of Canada to the value of $41,-194,000, against $44,800,000 in the previous month. On the other hand Canada's sales to the United States showed an increase of nearly a million and a half dollars. The import figures show goods valued at $10,875,000 were received from Canada, against $9,469,000 in October.

Advertisements of machine tools should contain complete information as to extra parts, fixtures and equipment; prices should be included. It requires clear, forceful technical copy and illustration. A matter of phraseology should be carefully considered; use of superfluous and flowery terms should be avoided. Co-operation between the engineering and advertising departments is imperative if satisfactory results are to be obtained.

The latest tendency in the textile industry has been upward. For the final month of the year 1921, the reports on the whole show expansion and greater activity, cottons, silk and ribbons all having an upward tendency. Increases are also reported in the Maritime Provinces. In Ontario and Quebec there were local fluctuations, with a net increase in employment. At Toronto, employment has been held at the September level. On the whole the financial outlook seems brighter.

It is stated that British Columbia now produces 37 per cent. of the lumber used in Canada. During the last 14 years, this part of Canada has increased its output 100 per cent., and the province's share of the saw-mill business in the Douglas Fir region has grown from about 8 to around 11 per cent. In 1920 it is asserted that nearly $93,000,000 of commercial material was produced, and the hundred million mark will probably be exceeded this year. Last year's output amounted to approximately two billion feet of wood product. Employees in mills and logging camps numbered about 20,000 men.

The Engineering Experiment Station of the University of Illinois, has issued a bulletin, No. 124, entitled "An Investigation of the Fatigue of Metals." This is a progress report of the first part of the investigation, having for its object the determination whether or not there exists any clearly defined relation between static properties and ability to resist repeated stresses. It having been decided not to enter the field of non-ferrous metals at this time, a series of tests of materials well scattered over the field of ferrous metals was made, and in most cases two or more distinct heat treatments for each metal were studied. The results of the tests, and the conclusions to be drawn therefrom are given in the above mentioned bulletin, copies of which may be had without charge by addressing the Engineering Experimental Station, Urbana, Illinois.

German tanneries, says the United States Commerce Reports, are producing calf skins, patent leather, and kid leather up to 65 or 75 per cent. of their prewar output. The tanners are receiving adequate supplies of raw hides and skins to keep the industry occupied. France is supplying 70 per cent. of the calf skins and 90 per cent. of the kid leather. Denmark and Sweden are other sources of supply; England sends additional patent leather, Russia virtually nothing. Labor conditions in the leather industry are satisfactory, with almost no unemployment. Present wages per hour of 6.25 to 8 marks compare with 1913 rate of 45 to 65 pfennigs per hour.

Mr. E. L. McColl, Canadian Trade Commisioner in Rio de Janeiro, says that the British are giving $70,000 for a permanent building for Imperial exhibit, at the Brazil Centennial Exposition which is to be held at Rio de Janeiro from Sept. 7th to Nov. 15th, 1922 The permanent building will not have an industrial exhibit. A temporary annex is to be added for holding products, space in which will cost exhibitors from £2 to £3 per square foot, and in which there is plenty of space available. Canadian requirements in space are requested at the earliest convenience. Mr. McColl believes that Canada should have an exhibit of manufactured goods, as Canadian products resemble, with a few exceptions, those of the United States. Something, he suggests, should be shown in such products as agricultural machinery, lumbering machinery, logging and railroad construction machinery, and in textiles, canned goods, chemicals, machine tools, electrical equipment and rails. Canadian manufacturers who are interested are invited to communicate direct with the Trade Commissioner in Rio de Janeiro.

The "Weekly Bulletin" says that H. M. Senior Trade Commissioner in Canada and Newfoundland has forwarded specifications which he has received from the British Legation, Santiago, Chile, for requirements for the Chilean State Railways. These are for:—

(1) Twenty-three cars, boilers, electric machinery, lamps, etc., tin and lead in ingots, ordinary bars, iron and steel tubes, etc., etc., for which public tenders are called for the 4th February, 1922, by the Chilean State Railways, to be opened at 10 a.m. on that day at the "Departmento de Materiales y Almacenes," Alameda Station, Santiago.

(2) Fish-plates and chairs for rails, for which public tenders are called for 16th February next, to be opened at 10 a.m. on that date at the above-mentioned department. Canadian firms interested in these specifications (which are in Spanish) may obtain copies on application to the Director, Commercial Intelligence Service, Ottawa (quoting file No. 27526).

Hoping to find oil for several years past the Commonwealth Government of Australia has offered a reward of £50,-000 to the discoverer of a payable oilfield in Australia. In addition the New South Wales Government offers a reward of £10,000 for the production of the first 10,000 gallons of natural mineral oil within the state. The oil position at present is that scouts are out in almost the whole of the four quarters of Australia hunting for the faintest indications of its presence, and bores have been put down in places where favorable features have been located.

selves. So far favorable results have not been achieved. Geologists are exceedingly cautious in their expressed opinions as to the possibilities of finding oil. It is quite possible that the desire to eliminate errors has made scientists somewhat chary of expressing too encouraging opinions. They have, however, gone so far as to say that complete and thorough surveys of certain parts of Australia, chiefly in the northwest portions, are eminently desirable, and that from a geological point of view the outlook is sufficiently hopeful to justify large expenditure in putting down many trial bores.

MONTREAL MARKETS

(Continued on page 42)

quotations. As trading has been light, no very concrete effects have been noticed. Just what changes will occur in quotations, trading, and general conditions surrounding the non-ferrous metals, early in the New Year, is a problem. The outlook, however, is for a gradual improvement starting the middle or latter part of January and continuing into the early summer. Shortages of stocks exist in many quarters and should an increased demand arise, it will be necessary to produce more ore and additional refining plants will start up, all of which have a tendency to upset any prophecies made in view of the present conditions and outlook.

The scrap metal markets are quite dull, but it is refreshing to see the spirit of optimism prevailing among the trade. Foundry activity is about the only real factor that will revive this department of the metal trade.

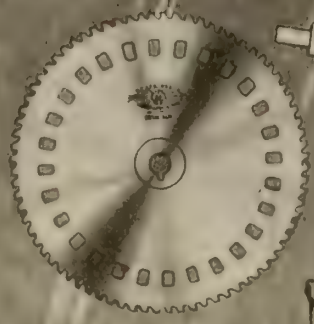
Of the 300 million acres fit for farming in Canada only one sixth is cultivated.

NEW USES FOR RUBBER

A very interesting competition was recently organized in Great Britain. Prizes were offered for suggestions for novel uses of indiarubber. About 10,000 suggestions were sent, and the first prize was awarded for the suggestion for using sponge rubber for general upholstering purposes, including the making of mattresses. Another prize suggestion was that rubber should be included in liquid form with paint or other composition for use in the preservation of wood and metals against the action of the sea. A third prize was given for the suggestion that rubber should be used for general decorative and preservative purposes. These and other suggestions are likely to create important new departments for British manufacturers.

NEW OIL GAS BURNER

A demonstration was recently given in London, England, of a new type of burner for use with oil. The oil is first converted into gas in a chamber filled with nickel gauze heated by the flame. The oil gas then passes through a regulating valve and issues as a jet which carries with it the air required for combustion. The mixture then passes into another chamber, where it is still further heated; and it issues from orifices arranged according to the services required. No carbon forms in the burner, and it does not require cleaning.



Railways in the United States have found that farmers along the rights of way are willing to haul old ties away for fuel and to perform some service in return, such as plowing fire guards, etc. This overcomes a problem which roads have had to face of late in as much as the increased cost of labor has made it too expensive for the companies to load and haul these ties to terminals for engine wood.

For Self-Promotion And Sales Promotion

Are you interested in any of these fields—power—metal working—marine? As a manufacturer, or purchasing agent, as a superintendent or foreman, as an ambitious mechanic or engineer?

Use These Publications

They will keep you strictly up-to-date in all branches of mechanical engineering. Edited by practical men. Cheerful, inviting, instructive, authoritative.

POWER HOUSE

Twice a month—$2.00 per year.
Serves the power plant engineer—Steam, Electric, Refrigeration, Hydraulic.

CANADIAN MACHINERY

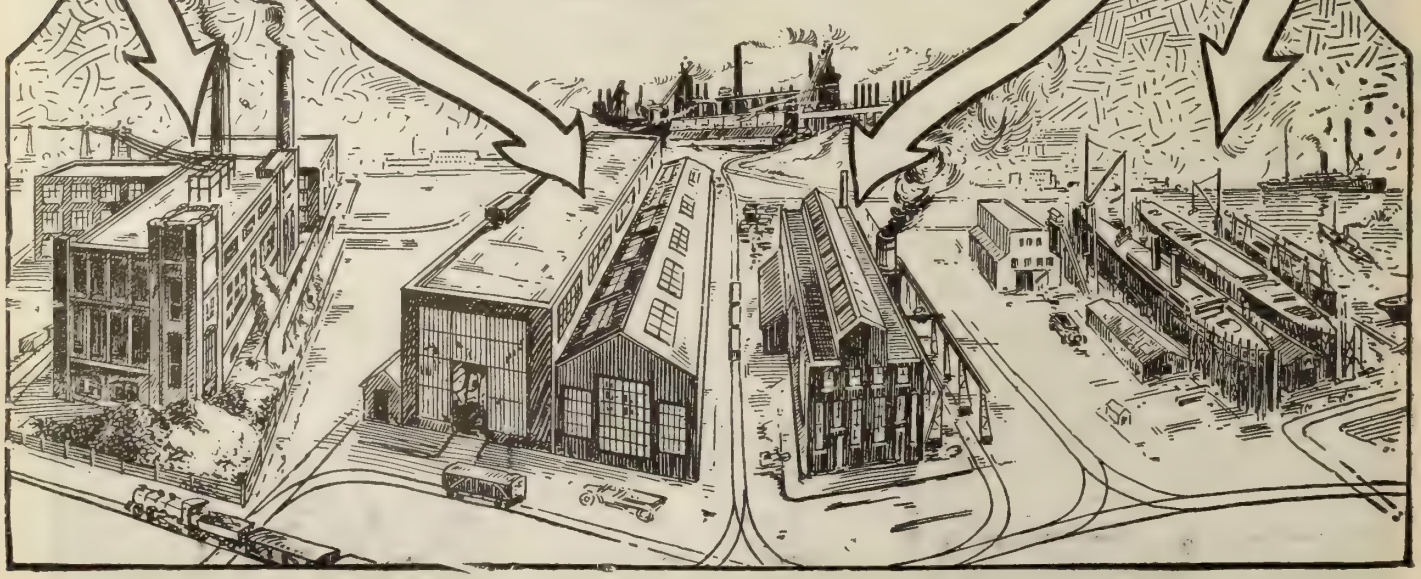
Weekly—$4.00 per year.
Covers the metal working field—serving shop executives, purchasing agents and owners. First-class mechanical paper and market paper combined.

CANADIAN FOUNDRYMAN

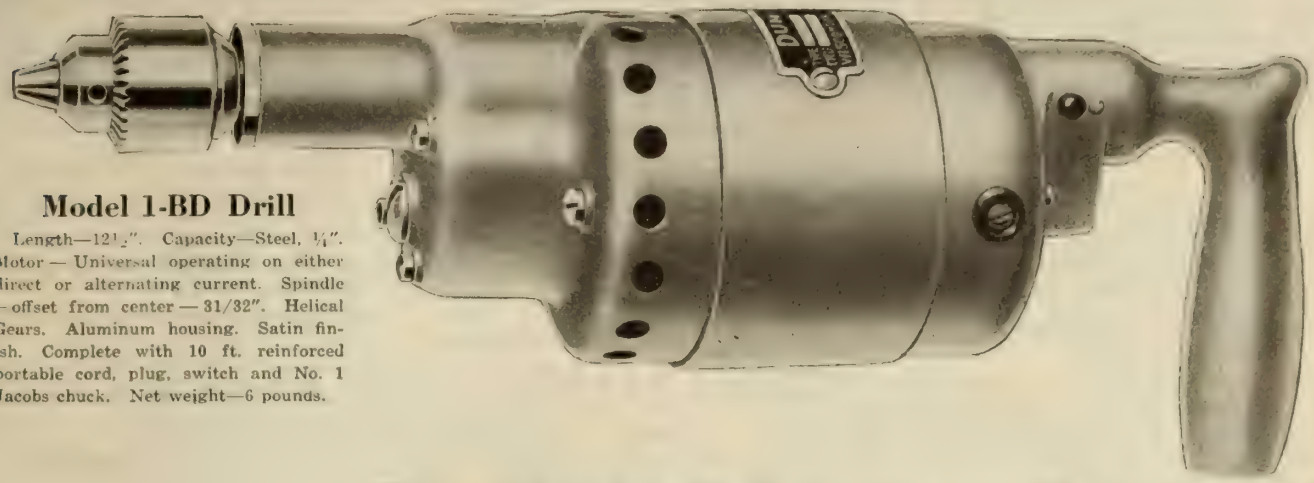
Monthly—$2.00 per year.
A paper for the foundry owner, superintendent and foreman. Claimed by its readers to be unexcelled.

MARINE ENGINEERING

Monthly—$2.00 per year.
Interprets marine engineering in its broadest sense, serving the shipbuilders, navigation companies and their officers. (The editor holds an extra first-class B.O.T. certificate.)



Published by

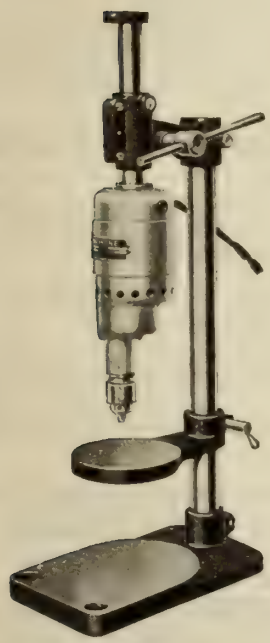


THE MACLEAN PUBLISHING CO., LIMITED

143-153 UNIVERSITY AVE., TORONTO

A company whose idea of service has made it the largest concern of its kind in the British Empire.
Thirty years' experience and dozens of practical men in your own line, stand ready to serve you. Let them! Subscribe for your paper to-day.

Men with selling problems will find a profitable tip in the statement made by a prominent manufacturer recently, "I use MacLean Publications because I am satisfied that papers with such a high standard of editorial excellence, MUST have an influential following."



Model 1-BD Drill

Length—12½". Capacity—Steel, ¼". Motor — Universal operating on either direct or alternating current. Spindle — offset from center — 31/32". Helical Gears. Aluminum housing. Satin finish. Complete with 10 ft. reinforced portable cord, plug, switch and No. 1 Jacobs chuck. Net weight—6 pounds.

Handy—Efficient—Powerful

Model 2-BD Bench Drill

Motor specifications identical with Model 1-BD.
Height—20½".
Stroke—3¼".
Rack and pinion feed.
Capacity—Steel, ¼".
Drills to center of 7⅞" piece. Ball Bearing thrust. Aluminum housing. Adjustable table. Complete with 10 ft. reinforced portable cord, switch, plug and No. 1 Jacobs chuck. Net weight 21 pounds.

DESIGNED by men who know the practical advantages of small, light tools that get to the spot where needed without waste of time, Dumore Drills save time, money and energy. Equipped with perfectly balanced motors, Dumore Drills are accurately built and have an almost unlimited range of usefulness. For speed and accuracy on fine and sensitive jobs Dumore Drills will supplement the work of your big machines—adding to the capacity of your shop and cutting down production costs on many classes of work.

Send for details of how you can use Dumore Drills to advantage.

Buying in Bulk

Grocers used to display their wares by placing them in bushel baskets on the sidewalk. In those days customers often paid for dirt when they were buying coffee.

Then came the day of standardized merchandise. Grocers gradually learned to sell their wares in sanitary packages trade-marked for definite quantity and quality.

Advertisers used to buy space in publications "in bulk." Like the old-time grocer's customers they frequently received as much refuse as "coffee."

The Audit Bureau of Circulations has done for advertising what standardized merchandise has done for the consumer. It has marked circulation with the stamp of accuracy.

In Canadian Machinery's circulation and advertiser buys a definite and known quantity. Its records are audited by the A. B. C.

MACHINERY FOR SALE

Lathes

U. S. ELECTRIC
Drills and Grinders
Can be Attached to any Lamp Socket

For drilling in metal these drills are the superior of every other kind of portable drill. Their operating cost is only half that of air drills. And they can be attached to any lamp socket.

A trial will prove that our drills and grinders will save you time, labor, and expense. Order a few to-day.

Made in several sizes from 3-16" to 1¼". Motors wound for alternating or direct current or both, 110 or 220 volts.

TRADE K–T MARK

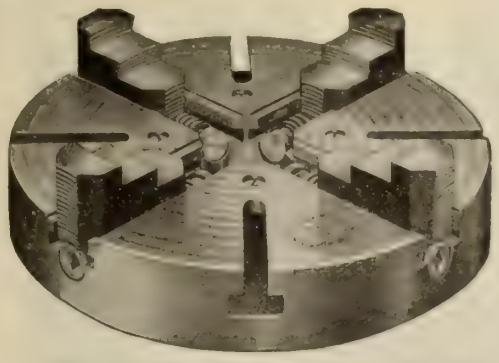
FOUNDRY
GALT, ONT.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.



We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

ALL STEEL

INDEPENDENT CHUCKS

are not an experiment—they have come to stay. They are a necessity with the modern machinery and high-speed steel cutting tools.

THE UNION STEEL BODY CHUCKS

are well designed and have all the elements of strength and durability for which they are designed. We make other types in steel also, including the Geared Scroll Chucks and the Geared Scroll Combination—all designed for heavy work and hard usage.

AN IMPORTANT QUESTION

For the Advertiser to Answer

Is the Publication Soliciting Your Business a Member of the Canadian National Newspapers and Periodicals Association?

YOU would never engage a man on an important piece of work until you gained a thorough knowledge of his qualifications. It would not be wise. You first of all require a clear record of his character and ability, in addition to a statement of his aims and aspirations. When you are in possession of this information you have a real basis for judging his fitness to serve you.

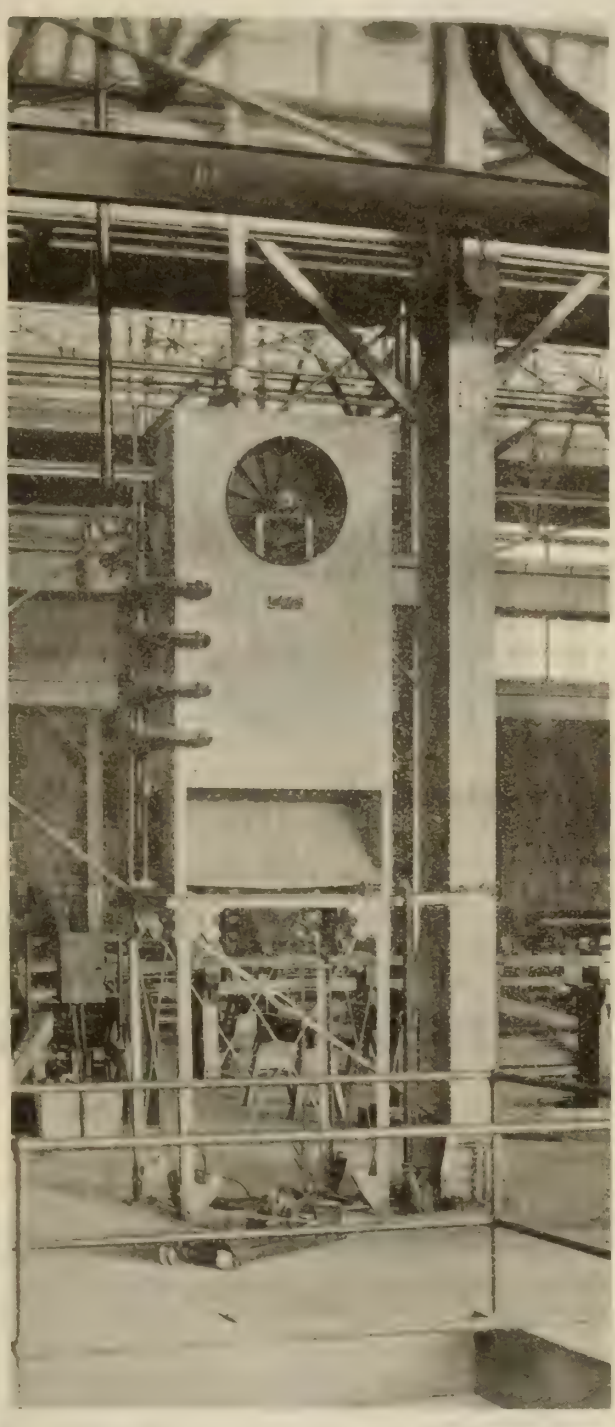
It is just as important that you should know the character, ability and aspirations of the publication in which you desire to carry your business message.

You should know if the paper is circulating and has an influence among those men who are responsible for results—the men who buy, or influence the buying, of machinery, tools, power and any other equipment or merchandise which you may sell.

Facts are essential. When you are in possession of the facts you can make every dollar spent for advertising a judicious investment. To enable the advertiser to make such judicious investment is the purpose of Canadian National Newspapers and Periodicals Association. From this Association the advertiser may secure complete information concerning the character and aims of the leading Canadian publications. The facts are fully presented for your consideration—and they are presented RIGHT.

CANADIAN MACHINERY

is a member of the Canadian National Newspapers and Periodicals Association, along with the following publications which constitute the Association's Technical Newspapers Section:



Canadian Engineer
Canadian Foundryman

Sturtevant

PUTS AIR TO WORK

20 UNIT HEATERS

are providing plenty of heat for the LeSalle Steel Company, North Hammond, Indiana.

These units maintain the temperature at 65 degrees above zero in the coldest weather.

The illustration shows one of the heaters in the finished material room. You will notice that the apparatus is placed above the floor, out of the way, where it does not interfere with the shop operations.

Placing these unit heaters in shops of any size causes very little inconvenience and a small amount of time and expense.

Thre is no more economical method of heating your shop buildings.

The Winter is not too far along to install Sturtevant Unit Heaters. Write any of our offices or representatives today.

Save Money on Screw Machines

Here's a way to effect a real saving on the work of your Automatic Screw Machines. Put this little detective on each machine and it will catch the loafers and the wasters.

Operators like it because it helps them to increase their production, and cuts out the nonproductive time formerly spent in counting by hand.

The Productimeter

Superintendents, production managers, and foremen like it because it enables them to plan work ahead, keep all machines always busy, and speed up production.

Executives like it because it cuts costs.

Hand Protection

Means Better Work

Mitten Style No. 681

Steel-Grip WORK MITTENS

and work gloves give complete hand **protection** plus hand **comfort.** The same reinforcement (small steel ribbons over strips of tough leather) that protects the hand also gives so much extra wear that these mittens and gloves last almost indefinitely. Sewed closed with steel thread, they are absolutely rip-proof. The steel reinforcement does not interfere with flexibility. Your workmen equipped with Steel-Grips will dig in with a will.

Write us to-day for suggestions on your hand protection problems. We can save you money on your work glove purchases.

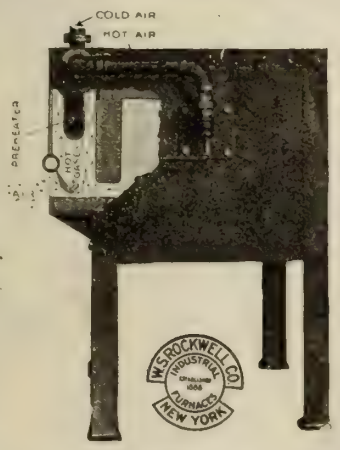
SPEND!

"THOSE who will not profit by experience deserve to suffer. Experience has taught thousands of successful business men that a dollar hoarded when it should be expended on advertising is worse than a dollar thrown away. This is particularly true of the time when the inclination to **conserve** is strongest."

Manufacturers of

HIGH GRADE SPRINGS, CARBON OR VANADIUM STEEL, BRASS OR BRONZE.

Our excellent facilities for the production and heat treating of Springs insure accuracy and durability.



Write for catalogue, also free engineering service on your spring problems.

Raymond Mfg. Co., Ltd.

Corry, Pa., U. S. A.

IDLE MEN IN FORGE SHOPS

(Patented)
Section showing deflection of hot gases, with induced air toward the furnace for protection of the operator and the preheating of air for combustion.

When men are idle, expensive equipment and buildings are also idle.

In past summers, the unbearable heat that caused prolonged shutdowns in many forge shops was **often due to faulty forges or improper application and utilization of the heat.**

To relieve these conditions, progressive forge shops are installing Rockwell Economizer Forges.

These forges enable the men to **work steadily and in comparative comfort.** They also afford other advantages in the way of **decreased operating cost, better quality of product,** and **decreased floor space.**

Write for Bulletin 239-T, dealing with improved methods of heating and handling material, layout of equipment, and other factors influencing the cost of production.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

Consult this Buyers' Directory when you want the names of reliable makers of machine tools, parts, steel, in fact any equipment you may need.

Procunier Safety Tapping Attachment

THE ONLY DEVICE ON THE MARKET HAVING A BALANCED REVERSING MECHANISM, thus eliminating all side pull or torsion. Its reverse speed is twice that of the forward speed. It has other features too we would like to bring to your attention. *Send for illustrated circular showing the*

Two generations of skilled machinists have learned to know Starrett Tools and to trust them.

Under the tuition of these men, thousands of apprentices are today learning for themselves the superior value in every Starrett Tool. No more conclusive evidence of quality could be asked than the marked preference for Starrett Tools shown by these men, to whose livelihood the selection of good tools is an essential matter.

2100 fine tools are described and illustrated in the new Starrett Catalog No. 22-3. Sent free on request. Write for copy.

BROWN & SHARPE MACHINISTS' TOOLS

The experienced mechanic knows the points of superiority in Brown & Sharpe Machinists' Tools that make a difference to his work.

The correct and carefully fitted parts, the clean cut graduations, the distinguishing finish, the world known accuracy, and long life are reasons why these fine tools are the skilled craftsmen's choice.

These superior tools—over 2,000 of them — are shown in Catalog No. 28. Every mechanic and manufacturer should have a copy.

BROWN & SHARPE MFG. CO., Providence, R.I., U.S.A.

If it's speed you need--

One trial will prove the advantage of Pratt & Whitney Milling Cutters. No matter what the nature of the work they will give you the highest production the machine is capable of.

They're designed for free, fast cutting. And tempered and seasoned to last longer.

PRATT & WHITNEY MILLING CUTTERS

Ask us for prices and details on Plain Milling Cutters, Side Milling Cutters, Inserted Blade End and Side Cutters, Screw Slot Cutters, Coarse Tooth Side or Plain Milling Cutters, Involute Gear Cutters, Concave, Convex and Double Angle Cutters, Cutters for Spiral Mills, Roll Thread Die Hobs, Key-Seating and Slotting Cutters, Straight and Spiral Cut End Mills (B. & S. and M. T. Shank), Spiral and Straight Shell End Mills, etc.

And we make formed cutters for special work also. All are backed by the guarantee for goodness that the P. & W. trademark indicates.

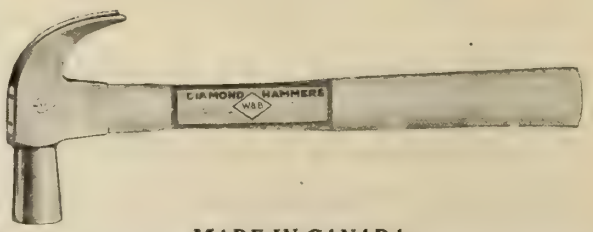
MADE IN CANADA

WILLIAMS' SUPERIOR Drop-Forged Hammers

Are dependable tools because:

THEIR heads, drop-forged from a special grade of tough steel, carefully hardened and tempered, neither crack, chip nor splinter.

They are fastened most securely and solidly to the handles—can't work loose—can't fly off.



Their handles are made of the best grade of clear, straight-grained hickory, flared at the grip to prevent hand-slip.

The weight and length of each tool are properly proportioned to give perfect balance, and, hence, increased striking power.

Williams' Superior Hammers of all kinds and sizes. Catalog on request.

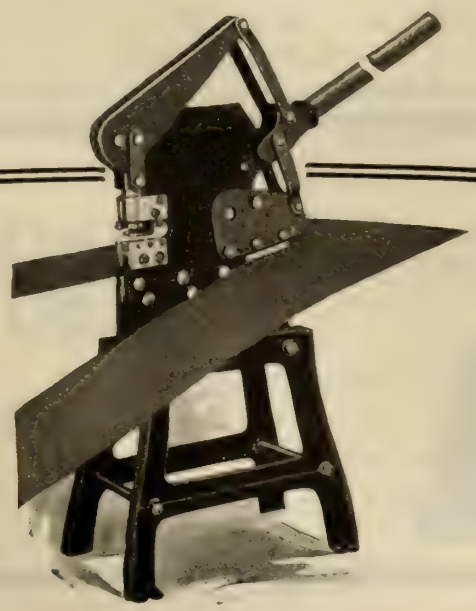
MADE IN CANADA

"CANADIAN"
HAND POWER PUNCHES AND SHEARS

All Canadian hand power Punches and Shears are made with "Armor Plate" frames.



This frame construction consists of a rolled steel plate having a tensile strength 7½ times that of cast iron. This strength permits of a machine much lighter and more compact than is possible with either cast iron or cast steel.

Let us know what your punching and shearing requirements are. We have an "Armor Plate" machine for the service. Remember our Armor Plate Air comprises power operated machines as well as hand power.

$50 Worth of Books for $3

Fifteen of the Best Sellers of the Year For $3 if you subscribe to MacLean's Magazine

During 1921 MACLEAN'S, Canada's National Magazine, has published the whole or major portion of the following fifteen books, which have since been published in book form—or are shortly to be published:

(1) Reminiscences of a Raconteur
—Col. George H. Ham
The recollections of Canada's premier story teller, the C.P.R.'s knight of wit and wisdom, who has known every person worth knowing in Canada during the past half century.

(2) Masques of Ottawa—"Domino"
A series of brilliant, biographical sketches of Canadians prominent in politics and business; analogous to "The Mirrors of Downing Street."

(3) Canada at the Cross-Roads
—Agnes C. Laut
A series of vigorous, inspirational articles showing how Canada is standing on the threshold of nationhood; constructive criticism indicating how full national status is being achieved.

(4) Policing the Plains
—Rev. R. G. MacBeth
The latest and most authoritative history of the Royal North West Mounted Police, by a padre who himself took part in the Riel Rebellion and has associated with many of the leading characters in Canada's famous frontier force.

(5) The Drama of Our Great Forests
—Arthur Heming
The pulsating, throbbing, human-interest story of Canada's great northern fastnesses, told by the man who will go five hundred miles to get a fact; authentic, enthralling.

(6) The City of Peril—Arthur Stringer
An up-to-date narrative of a Bolshevistic plot which was nipped in the bud by an adventurous young millionaire; including a delightful Stringer-like romance.

(7) Pawned — Frank Packard
A fast-moving story of a triple regeneration, shifting with kaleidoscopic speed from the South Sea Islands to this continent—novel, intense, gripping, mystifying.

(8) The Valley of Gold—David Howarth
The first novel from the pen of an athletic Methodist parson now resident in Miami, Manitoba—a true-to-life account of the Qu'Appelle Valley of Saskatchewan as it was twenty years ago; vigorously, thoroughly Canadian.

(9) Mostly Sally
—Pelham Grenville Wodehouse
A worthy successor to "The Little Warrior," told in the inimitably facetious and whimsical vein of this English master-craftsman.

(10) The Yellow Streak
—Valentine Williams
The story of a murder mystery solved by real human beings; from the pen of the author who wrote "The Man With the Club Foot."

(11) The Gates of Tien T'ze
—Leslie Howard Gordon
An enthralling book which ran in MACLEAN'S as a five-part serial; dealing with life in London when Anglo-Saxons and Chinese met at cross purposes.

(12) Lenix Ballister, Diplomat
—Archie McKishnie
A dozen short stories about the typical Canadian negro of Western Ontario; a forthcoming volume from the pen of one of Canada's foremost fiction writers.

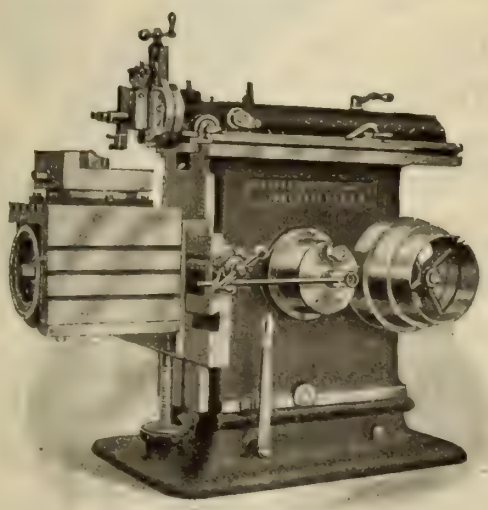
(13) Prince Renine
—Maurice Le Blanc
Eight more stories in which the leading character is the thinly disguised Arsene Lupin, one of the world's famous characters in detective fiction.

(14) A Series of Short Stories
—"Sapper"—H. C. McNeile
Ten or a dozen brilliantly written stories, impregnated with human interest, from the pen of one of the most successful English authors brought to the fore during the war.

(15) The Man Who Knew Too Much
—G. K. Chesterton
A collection of eight stories, each with its distinctive mystery, and containing the usual Chestertonian twist, from the pen of the man who wrote the "Father Brown" series.

Readers of MACLEAN'S got all these books in 1921—ten books of fiction and five of a more serious character, biographical, reminiscent, political—permanent literature.

In addition, they got a most attractive offering of the best short stories and the twice-a-month Review of Reviews department, which kept them posted on current topics and developments in all parts of the world, as well as the multitude of Special Articles on Topics of National Interest in Canada, which have made MACLEAN'S something more than a magazine—a National Institution.



MACLEAN'S readers got all this immense value in 1921—in 1922 they will get bigger value still. And you get all this for $3.00—the price of a year's subscription—24 twice-a-month issues of

MACLEAN'S

Self-Promotion And Sales Promotion

Are you interested in any of these fields—power—metal working—marine? As a manufacturer, or purchasing agent, as a superintendent or foreman, as an ambitious mechanic or engineer?

Use These Publications

They will keep you strictly up-to-date in all branches of mechanical engineering. Edited by practical men. Cheerful, inviting, instructive, authoritative.

POWER HOUSE

Twice a month—$2.00 per year.
Serves the power plant engineer—Steam, Electric, Refrigeration, Hydraulic.

CANADIAN MACHINERY

Weekly—$4.00 per year.
Covers the metal working field—serving shop executives, purchasing agents and owners. First-class mechanical paper and market paper combined.

CANADIAN FOUNDRYMAN

Monthly—$2.00 per year.
A paper for the foundry owner, superintendent and foreman. Claimed by its readers to be unexcelled.

MARINE ENGINEERING

Monthly—$2.00 per year.
Interprets marine engineering in its broadest sense, serving the shipbuilders, navigation companies and their officers. (The editor holds an extra first-class B.O.T. certificate.)

Published by

THE MACLEAN PUBLISHING CO., LIMITED

GOODELL-PRATT

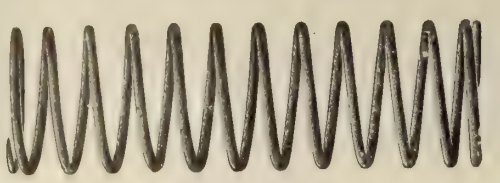
1500 GOOD TOOLS

DON'T TAKE ANYBODY'S WORD FOR IT—

Find Out For Yourself.

We believe that we are making the most accurate line of machinists' tools now on the market. But we don't ask you to believe us.

All we ask is that you thoroughly test Goodell-Pratt tools and find out for yourself. Tests that you can make yourself under your own working conditions will convince you more thoroughly than anything that we can do or say.



Whether it is a Micrometer, a Depth Gauge, a Steel Rule, a Square, or any other precision tool, we will stand squarely back of the materials and workmanship, and we guarantee the accuracy. The finish you can readily see for yourself, and the serviceability you will find out after years of use.

Ask your dealer, or write for "Tools for the Toolmaker"

More Speed
Better Work
With

16 and 20 inch Crank

McDougall SHAPERS

Modern methods of manufacture require modern tools. McDougall 16 and 20 inch shapers embody the best features of all machines which have been placed upon the market and can be depended upon to produce work accurately and fast.

An important feature is the column. It is massive in construction, well braced and reinforced internally. Has ample opening under ram for keyseating or other long work. Bearings for ram extend beyond vertical line of column both front and back. The ram is of exceptionally strong construction. McDougall shapers have other points of interest you should know about. Write for full description.

BROWN & SHARPE MACHINISTS' TOOLS

WHEN finished parts come up for inspection the unvarying reliability of Brown & Sharpe Machinists' Tools sets the standard by which the most exact work is tested.

YOU, the mechanic, whose work is gauged by this inspection, will secure more uniformly accurate results with the help of Brown & Sharpe Machinists' Tools.

THEIR enduring precision gives you the certainty that your finished pieces will pass the most rigid inspection and your reputation as a reliable workman will increase accordingly.

COMPLETE your kit with Brown & Sharpe Machinists' Tools.

YOU, the manufacturer, whose business success depends upon the accuracy of your tool equipment, should supply your tool rooms with Brown & Sharpe Machinists' Tools—tools you and your men know are accurate.

YOU will experience an increasing satisfaction in seeing the use of these reliable tools improve your production and diminish your scrap pile.

EQUIP your tool rooms with Brown & Sharpe Machinists' Tools and help your men to work with greater accuracy and confidence.

Over 2,000 of these superior tools are described in our Catalog No. 28. Send for a copy today.

Machining Locomotive Brasses on Boring Mill

Proper Fixtures Important If Maximum Production is to be Procured—Railroad Shops Find Many Uses For This Type of Machine Tool—Machining a Nine Inch Globe Valve

*By J. H. MOORE

IN THE September 15th, 1920, issue of Canadian Machinery, we published an article on Vertical Boring Mill work. As these machines have become very popular during the past few years, we feel that further examples of work performed on this type of machine would not be amiss.

In a short article of this nature we can only touch on a few scattered examples, but readers will no doubt be able to supplement the operations shown by experiences of their own. Unfortunately, a few mechanics still look upon the vertical boring mill as a production tool only. This is an erroneous idea, for while such tools are ideal for production purposes, they must not be overlooked as general purpose machines. In manufacturing plants, automobile factories, and so on, they would be used as production factors. Operations in such cases are laid out very carefully, and usually the work passes down a regular line of machines until completed. The operator takes his work off the mill, places it on a gravity conveyor, gives it a slight push, and on it goes to the next operation. Under such circumstances the machine can well be termed a production tool. But in the case of the general machine shop, or a plant where locomotives are built or repaired, the vertical boring mill is likewise useful. True, only a few pieces may be completed in a batch, the nature of work being changed several times a day, but this in itself merely proves the versatility of the tool. The writer at one time operated a mill which usually produced eight different styles of work inside the ten hours.

*We are indebted to the Bullard Machine Co., for the use of the illustrations in this article.

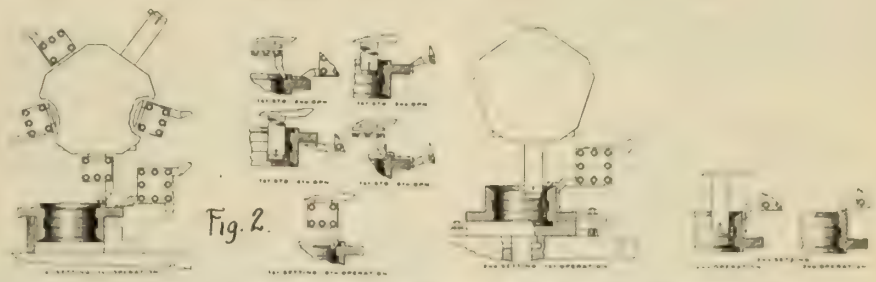

Fig. 2—Showing Set Ups For Machining Packing Glands.

To make the most of a boring mill, or in fact any machine tool, intelligent operation is essential. The operator should make it a point to become thoroughly conversant with the proper style of tool to use on the different operations. He should see that he is supplied with suitable jigs for holding the work quickly, and when the quantity does not warrant a special fixture, he should devise some simple method of holding the work. The foreman and operator can often get together to good effect, the discussion bringing out some further improvement. When the plant is large, the tool designer usually takes over this responsibility, but here again it will pay the designer to co-operate with the foreman whenever possible, as the shop point of view should not be ignored.

Some Railroad Work

We will first consider some parts which have been machined in railroad shops. Fig. 1 shows, in photographic form, a cylinder head being finished. These parts are subjected to considerable

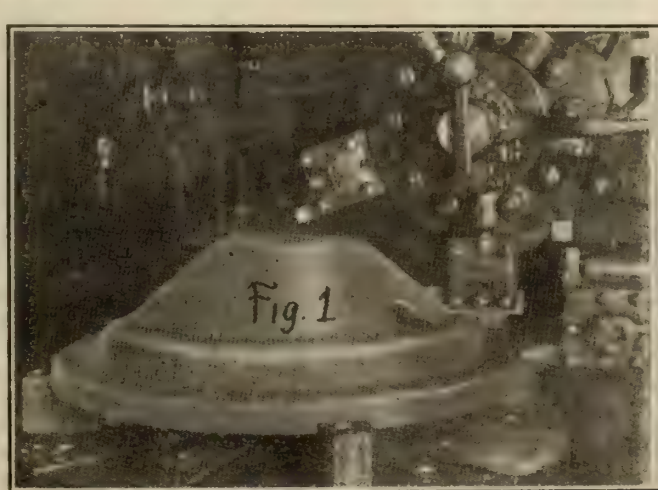

Fig. 1.—Machining a Cylinder Head.

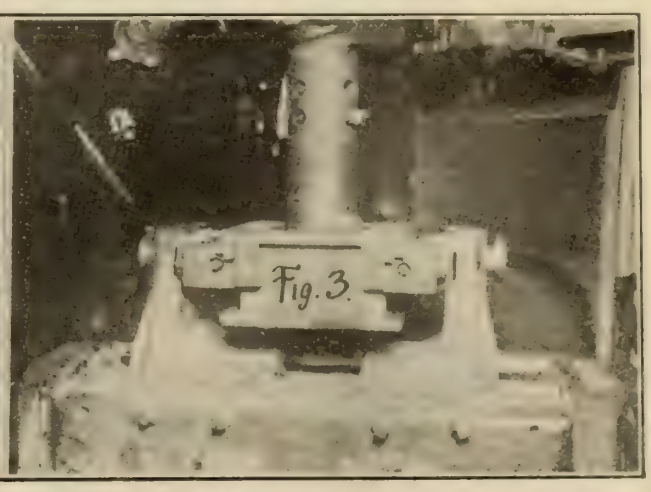

Fig. 3—Producing Locomotive Brasses.

wear, and are often required quickly to replace breakages, worn-out heads, etc. Note the simple yet efficient type of form tool used. The design varies considerably, so that the versatility of a boring mill is useful on such work.

A very good method of machining packing glands is shown at Fig. 2. It will be noted that in this case we have a combination of boring, turning and facing operations. Two settings are required, the first taking care of six operations or steps, the second completing the other three. The turrets clearly show the various tools required, and the arrows indicate the direction of movement. When the tooling is properly laid out, the two heads can work continuously without interference. This bears out our previous remark viz., that the study of the proper tools to use is most important.

Fig. 3 shows one method of machining locomotive brasses. Note the simple type of chuck used on this work. It holds the brasses, quickly, and releases just as rapidly. As the type of boring bar used is very simple we need comment no further.

Machining Sprocket

The use of the side head is well illustrated in the remaining sectional views. Take for example Fig. 4. Here we see a sprocket being machined all over, this part being made from octagonal boiler plate. The tool layout being so clear we will pass on to Fig. 5. In this case the work being produced is a steam engine piston. The surfaces finished are clearly shown and as will be noted the piston rod hole is tapered in the regular manner.

Fig. 6 depicts a flywheel being machined. Note the tool layout, also the arrows which show the direction of rotation and feed.

At Fig. 7 we see a gear blank being machined, while at Fig. 8 is shown another type of flywheel being produced. The tooling in the latter case is well worth studying. The machining time can always be cut considerably by careful tooling.

The remaining illustration, Fig. 9, shows a 9 in. globe valve being machined. Again we see the advantage of side head working in conjunction with the main head. The variety of parts which have been shown is very meagre when viewed in comparison with the possibilities of vertical boring mills, but the success of such tools becomes all the greater when coupled with careful tool and fixture planning.

WATER POWER AVAILABLE

Professor Gibson, in addressing the Section of Engineering on "The Development of Water Power" at the British Association meeting in Edinburgh, said that the available horse-power of the world from the water was of the order of 200,000,000, of which approximately 25,000,000 were at present developed or in course of development. Great Britain, with 900,000 available, had developed only 200,000, the total available and amount used being the smallest of any country for which figures were known. Canada used, or was about to use, over 3,000,000 out of a possible 23,000,000, the remainder of the British Empire 700,000 out of a possible 30,000,000 to 50,000,000, the United States of America nearly 10,000,000 out of 28,000,000, France 1.6 out of 5.6, Germany 0.75 out of 1.5, Japan 1.5 out of 8 possible millions. The inland water resources of the United Kingdom were capable of supplying 27 per cent. of the horse-power that was represented in the total annual consumption of 55,000,000 tons of coal for industrial purposes, excluding railways and steamships.

ELECTRIC RUN-ABOUT CRANE

British cranes of every type are well known and it is not surprising to find a constant improvement being made. At a recent exhibition held in London a new type of run-about crane, propelled and operated by an electric battery was shown. The crane itself lifts 15 hundred weight at the rate of 20 feet per minute, and is stable in any position without anchorage. The jib has a rising and falling motion only, slewing action being obtained by rotating the whole machine on the ground. The structure carrying the jib is placed on a chassis which is roughly circular and has driving wheels at each side driven by separate motors, as well as steering wheels fore and aft. These wheels are so arranged that the whole truck will rotate in a circle little over 6 ft in diameter. The battery, which acts as a counterpoise, is capable of propelling the loaded crane at 300 feet per minute.

Designing an Effective Trussed Beam

A Thorough Understanding of the Strains Imposed Upon the Various Parts of the Beam is Essential—Diagrammatic Views Showing Different Conditions

By JOHN S. WATTS

FOR relatively long spans, and medium loads, the trussed beam is very frequently the most economical, but, probably owing to the average designer being rather unfamiliar with this type, other forms of beams are more commonly used which are not so efficient. To design a really effective trussed beam, it is essential to have a thorough understanding of the strains imposed upon the various parts of the beam, and not to erronously assume that a beam that is nearly strong enough to carry the load as a simple beam, will with the addition of a truss rod which looks about right as to size, be strong enough, as I have known some people to do.

As will be shown more clearly further on in this article, the main part of a trussed beam, acts as a strut, and therefore its whole sectional area is in compression, unlike the plain beam which is under compression on one side of its neutral axis, and tension on the other side. The strength of a section used as a plain beam, is therefore no criterion of its strength when used as part of a trussed beam.

Figure 1 shows diagrammatically the form of a trussed beam, the heavy lines indicating the parts in compression, the light lines, those that are in tension. It is clear that for such a beam to fail, the

$$S = \frac{w \times l}{D}$$

load must be sufficient to deform it as shown in figure 2.

A study of the two figures shows that the beam fails by the parts AB, BC, or CD, being too weak to stand the compressive strain, or because parts AF, FE, or ED, pulled apart under the tension, or the parts BF or CF failed under the compression.

To determine the strains on each of these parts, we will take the simplest case first; that is when the load is in two equal parts concentrated at points B and C. The moment of the weight w, at point C, is equal to w x 1, and is resisted by the tension in FE, which has a leverage equal to D. Calling s the tensional strain on FE, we have:

See cut No. 1.

By the same reasoning it can be shown that the compressive strain on BC, is the same as the tensional strain on EF.

To find the strains on the parts CD, DE, and CE, we lay out the triangle of forces as in Figure 3, the lines being parallel to the lines having the same letters in Figure 2, and the Line CE, being made to scale to represent the weight k. From this we find that the strain on CE, is compressive and is equal to w, the compression on CF is the same as that already determined for BC, and we can scale off the tension on DE, which will be slightly greater than that on the horizontal part of the tie rod FE.

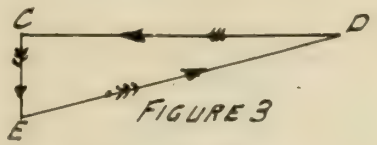

FIGURE 3

Obviously the greater the depth D is made, the less will be strains on all the parts except DE, and therefore the most economical truss will be that having a depth D, as great as can conveniently be made without reducing the head room under the truss too much.

The parts BC, CD, and DE, being under compression, must be designed to carry their load as columns, and the safe stress which can be placed upon them must be based on the ratio of the radius of gyration of the section to the length BC, CD, or DE, respectively.

The tie rod AFED, being in tension, is usually made of a circular bar, threaded at both ends and fitted with a turn-buckle in the central horizontal part to ensure that it will be tight, and so carry its proper share of the load.

The struts BF, and CE, are commonly made of cast iron, as they are not heavily loaded, and this makes it simple to get the required seat for the tension rod. The usual style is that shown in Figure 4.

When the load is concentrated, as in Figure 1, it is obviously desirable to place the struts BF, and CE, directly under the loads. But when, as is more common, the load is uniformly distributed, the length l is preferably made one-third of the span L, because the parts AB, BC, and CD, being all columns under the same load, will then be all of equal length, and therefore of equal strength.

To calculate the strains for a beam loaded with a uniformly distributed load, it is necessary to convert this load into its equivalent as a concentrated load at the points B, and C.

The bending moment for a uniformly distributed load being WL/8, and that for the two symmetrical loads as in Figure 1, being wl, where W is the total distributed load and w, the equivalent concentrated load it follows that if the two bending moments are to be equal:

$$wl = \frac{WL}{8}$$

$$\text{but } l = \frac{L}{3}$$

$$\therefore w \times \frac{L}{3} = \frac{WL}{8}$$

$$w = \frac{3W}{8}$$

The equivalent concentrated load at each point B and C, is therefore ⅜ of the total distributed load, the remaining part of the load being borne directly on the supports at the ends of the beam, that is ⅛ of the load on each support.

In addition to the strain which the parts AB, BC, and CD, carry as columns, there is also the strain imposed upon them by reason of their carrying the distributed load as beams between the points of support A, B, C, and D. This stress must be calculated and the compressive stress on the upper side of

Elements of Machine Design—Lesson No. 4

In the Design of a Column Bracket Various Factors Must be Considered Such as the Rivets in Top Horizontal Angles—Rivets Through Web and Vertical Angles of Bracket

*By L. T. RUTLEDGE

CONTINUING lesson No. 4, from the December 15th issue, we find that after developing the theory spoken of on page 21 of that issue, it may be interesting to determine the stresses for a standard beam connection as given in two of the best known steel maker's handbooks. Fig. 20 shows the connection recommended for a 12 inch I—beam as copied from a 1912 edition. The 12 inch x 40 lb. I—beam calls for two 6 x 4 x ⅜ inch angles 7½ inches long. The same book gives for a span of 10 feet 43,720 pounds as the safe load uniformly distributed, so that the maximum fibre stress shall not be greater than 16,000 pounds per square inch.

Assuming the above loading, the end reaction will be 21,860 lbs. The direct shear on each rivet is 21,860 or 43,720 lbs.

The value of the turning force

$$T = \frac{Pa}{\sum d^2}$$

$$= \frac{Pa}{d_1^2+d_2^2+d_3^2+d_4^2+d_5^2}$$

$$= \frac{21860 \times 3.375}{1.125^2+2.74^2+1.59^2+1.59^2+2.74^2}$$

$$= 3455 \text{ Lbs.}$$

The secondary stresses on the various rivets are as follows:

On rivet No. 1=Td$_1$=3455x1.125=3887 lbs.

On rivets 2 and 5=Td$_2$=3455x2.74=9467 lbs.

On rivets 3 and 4=Td$_3$=3455x1.59=5493 lbs.

It is apparent that rivets 2 and 5 are the most highly stressed and it will be necessary to deal with them alone. Adding 4375 lbs. and 9467 lbs. vectorially, we get 11940 lbs. The safe value of a ¾ inch rivet in double shear is 8836, whereas the bearing value against the web of a 12 inch I—beam which is 0.56 inch thick is 8400. The latter value, being the least value, governs. The analysis shows that rivets 2 and 5 are stressed 40 per cent. above their safe value. Calculating the actual unit stress in the ¾ inch rivet, we find it to be 27100 lbs. per sq. in.

In the more recent editions of the steel hand-book, it is interesting to note that the end connections of many sizes of beams have been re-designed and for the particular case in question, it is now recommended to use two 4x4x7/16 inch angles 8½ inches long and furthermore only three ¾-inch rivets are specified. The intention in the latter design is to reduce the values of the secondary stress due to the eccentricity.

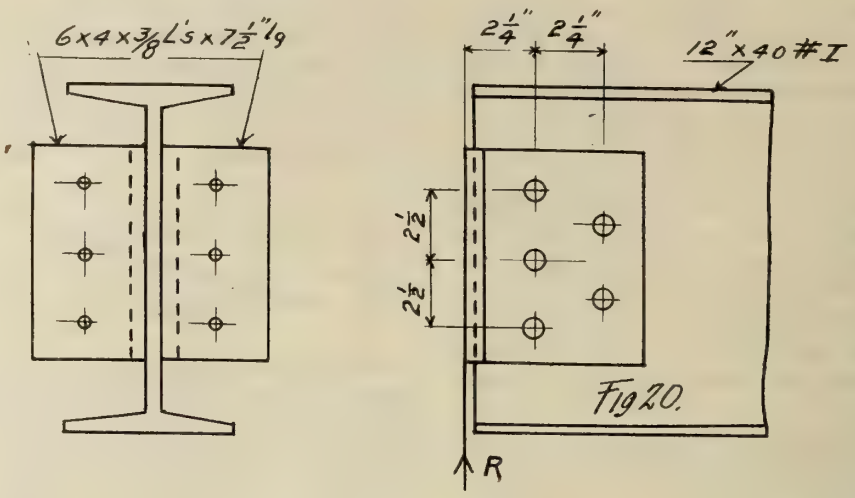

Fig 20.

4. Design of a Column Bracket

Fig. 21 illustrates a column bracket designed to carry a crane beam. The bracket is attached to a column consisting of four 5x3½x⅜-inch angles placed 14¼ ins. back to back and riveted to a 14x⅜ inch web plate, with their longer legs turned outwards. A 15-inch

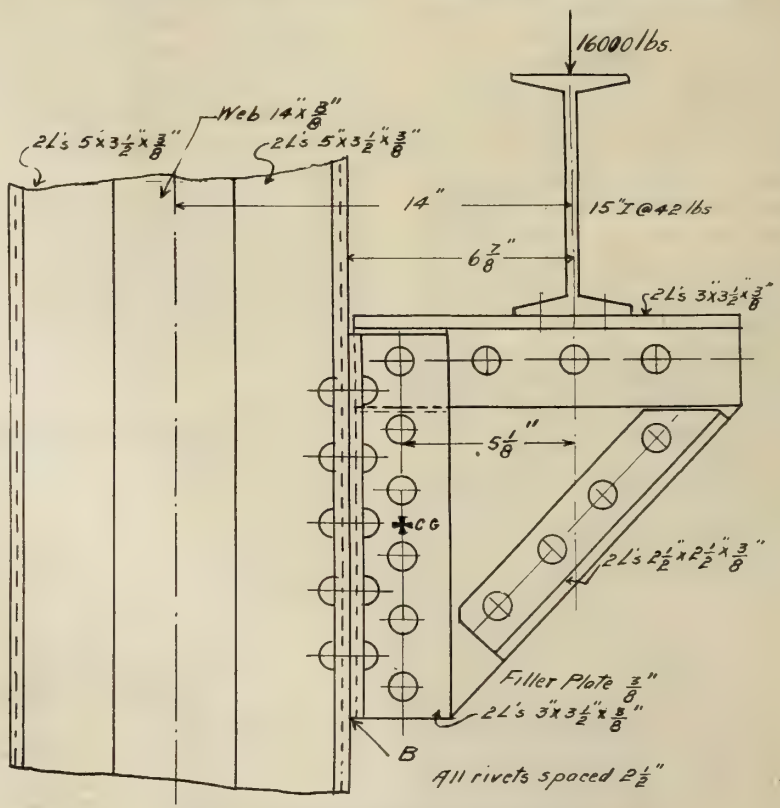

Fig 21.- Sketch of Steel Fabricated Bracket

*The author is Professor of Mechanical Engineering at Queen's University, Kingston, Ont., and should any reader wish help in any problem on mechanical matters, Mr. Rutledge will be only too pleased to offer assistance. To save time, write direct to Kingston, explaining your trouble in detail.

I—Beam at 42 lbs. at right angles to the web of the column and 14 ins. from the centre line of the latter rests on the bracket. The assumed reaction is 16000 pounds. All rivets are ¾-inch diameter. In the bracket design, the following items are used:

2—top angles 3x2½x⅜ inch
2—vertical angles 3½x3x⅜ inch
2—stiffener angles 2½x2½x⅜ inch
1—web plate ⅜ inch.

It is required to design the riveted connections.

(1) Consider the rivets in the top horizontal angles.

Taking the least value of the ¾-inch rivet in double shear to be 8836 lbs. and in bearing against the ⅜-inch plate to be 5625 lbs., we find that, owing to the absence of eccentric loading in these angles $\frac{16000}{5625}$ or 3 rivets will satisfy.

So use 3 rivets spaced symmetrically relatively to the centre line of the I—beam as shown in Fig. 21.

(2) Consider the rivets through the web and the vertical angles of the bracket.

Assume 6 rivets. The direct shear on each rivet is $\frac{16000}{6}$ or 2667 lbs.

Here it is apparent, we have a case of eccentric loading.

The distance from the centre of gravity of the riveted area to the line of action of the force is 5⅛-inches. The turning moment on the connection is 16000x5⅛ or 82000 inch—lbs. Using a rivet spacing of 2½ ins., the turning force on the extreme rivet

$$= \frac{Pa}{\sum d^2} \times d_1$$

$$= \frac{82000 \times 6.25}{2\{1.125^2 + 3.375^2 + 6.25^2\}}$$

$$= \frac{82000 \times 6.25}{109.375}$$

$$= 4685 \text{ Lbs.}$$

Combining the direct and secondary stresses we have the maximum stress

$$= \sqrt{2667^2 + 4685^2} = 5390 \text{ Lbs.}$$

is a trifle less than the least value of the ¾-inch rivet. The assumption of six rivets spaced 2½ inches centre to centre was quite correct.

(3) Consider the rivets through the column and the vertical angles.

Assume 5 rivets in each vertical leg spaced 2½ inches apart and staggered relatively to the rivets in the other legs of the angles.

The direct force on each rivet will be 1600 lbs., there being 10 rivets to take the shear. The rivets are also in tension and 7000 lbs. per sq. in. may be taken as a safe value in tension. The least value of a ¾-inch rivet in tension is 3090 lbs. The turning moment of the load on the rivets is 16000x6⅞ or 110,000 inch-lbs. The joint tends to revolve about the point "B" as shown in Fig. 20. In this case, it will be reasonable to consider the four rivets at the top to be the ones called on to resist the tension. "d" for the extreme rivet is 14 ins. and for the second one 11½ ins. Then the secondary stress on the extreme rivet

$$= \frac{110000}{2(11.5^2 + 11.5^2)} \times 14 = 2346 \text{ Lbs.}$$

When the direct stress of 1600 lbs. is combined with the secondary stress of 2346 acting at right angles to the direct stress we get a combined stress of 2840 lbs. which is a little less than the safe value of the rivet in tension. Thus we will accept this number of rivets as being what is required.

(4) Consider lastly the stiffener angles.

The stiffener angles are used to keep the bracket web plate from buckling. The stress is a compressive one. Four rivets will be quite sufficient. No complex calculations are required in this case.

(5) A Fastener with Eccentric Loading

In Fig. 22 is shown diagrammatically an ordinary radial drill with a rectangular base. The column part of the drill is fastened to the cast iron base or bed with 8 cap screws which are located by the numbered holes 1 to 8 on the plan of the base.

When the drill is working, a thrust "P" will be brought into existence and its point of application will be at right angles to the drill arm and will act upwards as shown. The point of application of this thrust will depend on the position of the work. Let it be distant "L" from the left hand edge of the base at the point "A." When the thrust comes upon the drill, the tendency is to tip the column of the drill backward about the point A. This is due to the turning moment PL. For equilibrium this turning moment must be balanced by the resisting moments of the stresses in the screws about the same point.

Assume the loads coming upon the screws are Q_1, Q_2, Q_3, etc., and let the distances of the screws from A be l_1, l_2, l_3 and l_4 as shown. Then for equilibrium

$$PL = 2(Q_1 l_1 + Q_2 l_2 + Q_3 l_3 + Q_4 l_4)$$

Multiplying by 2, since there are two rows.

Now the stresses induced in the screws vary directly as the elongations; thus it must be apparent that the loads on the screws vary. Screw No. 4 has to stretch more than screw No. 1. The elongation in any two screws is directly proportional to the distance from A. Therefore we have the following relations

$$Q_2 = Q_1 \frac{l_2}{l_1}, Q_3 = Q_1 \frac{l_3}{l_1}, Q_4 = Q_1 \frac{l_4}{l_1}$$

Substituting these values in the equation of moments above, we have

$$PL = 2Q_1 \left\{ l_1 + \frac{l_2^2}{l_1} + \frac{l_3^2}{l_1} + \frac{l_4^2}{l_1} \right\}$$

$$= \frac{2Q_1}{l_1} \{ l_1^2 + l_2^2 + l_3^2 + l_4^2 \}$$

$$\text{so that } Q_1 = \frac{PL l_1}{2\{l_1^2 + l_2^2 + l_3^2 + l_4^2\}}$$

$$\text{but } Q_4 = Q_1 \frac{l_4}{l_1}$$

$$\text{Then } Q_4 = \frac{PL l_4}{2\{l_1^2 + l_2^2 + l_3^2 + l_4^2\}}$$

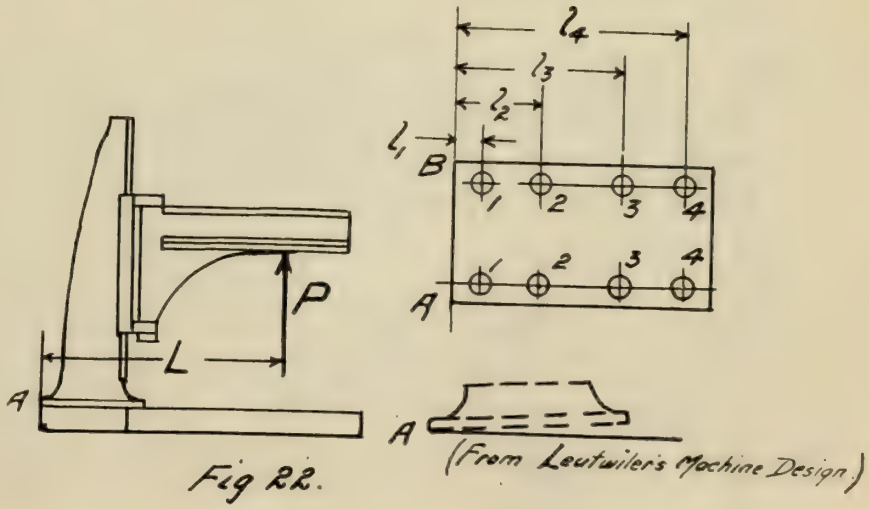

Fig 22.

(From Leutwiler's Machine Design)

and since the elongation in No. 4 is greater than in any of the other screws, the stress Q_4 is greater than that in any of the other screws.

In an actual problem where the thrust and the lengths are given it is a simple matter to solve for the value Q_4. The size of screw is determined by dividing the stress in the screw by the working stress for the steel of the cap screw. Since a radial drill is subject to shock loads, a factor of safety of 10 is recommended. Remember also, that the area of cross-section obtained will be the area at the root of the thread. So with this information, it is an easy matter to obtain the proper size of cap screw. The maximum will govern and they should be all alike.

The solution for a drill with a circular base is quite similar to the one for the rectangular base.

Where 2a is the outside diameter of the circular base and 2b is the diameter of the bolt circle, then the maximum load on a bolt, where six bolts are used to fasten the drill will be

$$\frac{PL}{3}\left[\frac{a+b}{2a^2+b^2}\right]$$

The student is recommended to attempt the derivation of this formula and if possible obtain a complete solution, being quite similar to the one given for the rectangular base.

It is also recommended that the student work the following problems:

1. For the riveted connection shown in Fig. 23, determine the stresses coming upon each rivet used for fastening the bracket to the column. Assume the magnitude of the load P as 4000 lbs. and the diameter of the rivets as ¾ ins.

2. Design the fastenings of a radial drill with a rectangular base 2 ft. x 3 ft. of similar appearance to the one shown in Fig. 21. Assume the thrust to be 3000 lbs. and the distance L as 60 inches.

EFFECTIVE TRUSSED BEAM

(Continued from page 19)

the beam must be added to the main compressive stress calculated as being imposed by the formulae

$s = \frac{Wl}{D}$. As the tensile stress on the under side of the beam reduces the main compressive stress, it may be neglected.

As all three parts AB, BC, and CD are under the same loads, and for simplicity are made of the same section, it is only necessary to calculate for one section. The stress will be determined from the formulae for a beam loaded with a uniformly distributed load, and supported at each end as follows:

$$\frac{W}{3} = \frac{8fz}{2} \quad \therefore f = \frac{Wl}{24z}$$

Where f= stress per square inch 'S
W= total load as before, but as each part as AB, is one third of the total length L, the load on AB will be —

$\frac{W}{3}$

z= Modulus of section.
1= length of part AB.

In general the beam will be made of a channel or I beam section or if of wood, of a rectangular section having the larger side vertical. Hence it will usually be found that having regard to the larger radius of gyration of the section in the vertical plane this additional stress will not bring the total stress above the allowable maximum. In other words if the truss is made of a channel section as shown in Figure 5, the strength of the part AB, as a column is fixed by its radius of gyration on the plane xx, the allowable stress being in accordance with the ratio of this radius of gyration to the length l. The radius of gyration on plane zz being larger will permit us to use a higher stress, so long as the additional load acts vertically only, and therefore if the total of the two stresses, that calculated as a column, plus that due to the part acting as a beam, do not exceed this higher permissible stress the beam will be safe.

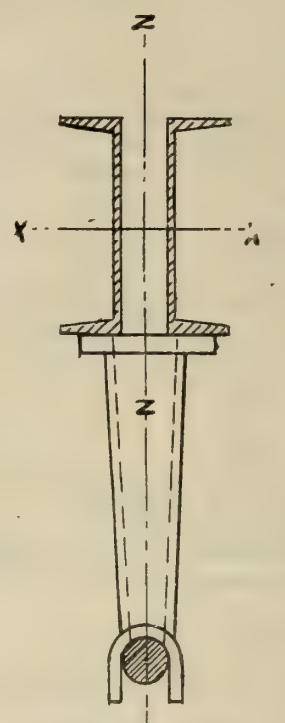

FIGURE 4

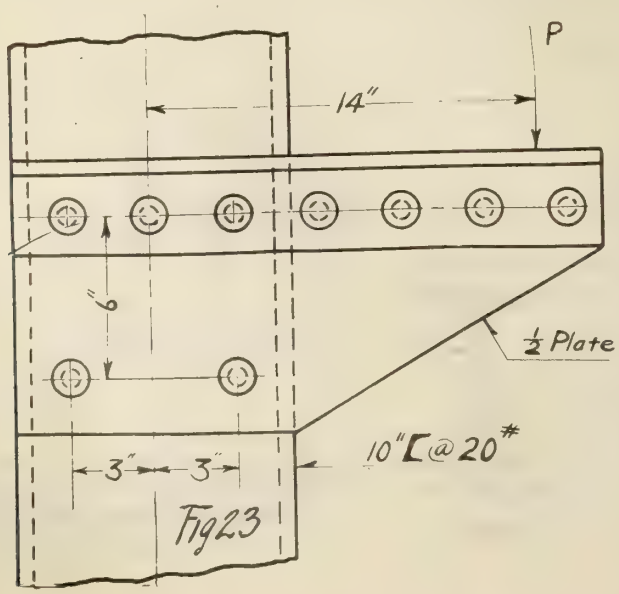

Fig23

NEW MINE RESCUE APPARATUS

Ever since the invention of the Miner's Safety Lamp by Humphry Davy, Great Britain has devoted keen attention to the subject of safety devices in mines. Experiments recently conducted by the British Scientific and Industrial Research Department have resulted in the design of two new types of rescue apparatus which are proving most successful. Both types of apparatus are what is known as "regenerative"; that is to say, the air expelled by the lungs is purified, supplied with oxygen, and returned to the lungs. Therefore, when a man wears this apparatus he is able to enter smoke or poisonous atmosphere without suffering ill effects. The apparatus and the lungs really form a closed circuit, and the lungs serve as a pump to circulate the air round that circuit. In one type of apparatus the oxygen is supplied from liquid air and in the other type it is obtained from a solution of compressed gas. Both pieces of apparatus are designed to enable the wearer to undertake continuous heavy physical exertion for at least two hours. As a matter of experience they can satisfy all the breathing needs of the wearer for three hours.

To Get the Best Out of a File—Treat It Right

Clogging of Teeth Should be Avoided Otherwise Greatest Efficiency Will Not be Secured—There Are Times When Oil Must Not Be Used—How to Economize on the Wear of a File

*By J. H. MOORE

CONTINUING the article on filing which appeared on page 25 of last week's issue, we come to the use of the file on lathe work. When used for shafting or lathe work the file should be constantly stroked against the turning of the revolving work, applying the pressure to the forward stroke, relieving it on the return stroke and giving the stroke a slight gliding or lateral motion to assist clearance of chips and to avoid filing ridges or scores.

For machine filing a special file is usually required and, where any very hard service is called for, the formation of the teeth should be such as to meet this special work. It must be remembered that files are almost always made with the intention that they are to be used by hand. The natural tendency of the workman to apply the pressure as required—to keep the file cutting or down to its work, using less pressure on the first strokes, (which prevents the finely shaped tooth point from being broken and dulled) and gradually increasing the pressure as the teeth lose their keenness—is in contrast to the fixed pressure of the machine and must be compensated for in the manufacturing of machine files. It is a well known fact that a file soon becomes dull and worthless if it be constantly stroked over the work without being held to it by pressure enough to keep it cutting. The hand workman's "feel" gives him the advantage over the machine at this point. However the importance of the work to be done must outweight the economical use of the file and when the machine is required it should be used and the file maker can produce teeth of the shape that will be far more effective for machine work than the ordinary stock file.

Drawfiling

Files are sometimes used for grasping at each end and moving them sidewise across the work, after the manner of using the spoke-shave. This operation is known as drawfiling and is usually performed in laying the strokes of turned work lengthwise, instead of circular, as left from the lathe finish, as well as when giving a final fit to the shaft that is to reveive a coupling: cases, generally, in which no considerable amount of stock is to be removed, and thus any defects in the principal of construction of arrangement of the teeth of the file are not so readily apparent.

Files as they are ordinarily made are intended to cut when used with a forward stroke, and the same file cannot work smoothly or to the best advantage when moved sidewise, unless care is taken that the face of the teeth present themselves, during the forward movement of the file, at a sufficient angle to cut, instead of scratching the work. To accomplish this, the angle at which the file is held with respect to the line of its movement must vary with different files, depending upon the angle at which the last or up cut is made. The pressure should also be relieved during the back stroke, as in ordinary filing.

When properly used, work may be finished somewhat finer and the scratches more closely congregated than in the ordinary use of the same file: as, in drawfiling, the teeth produce a shearing or shaving cut.

In economizing the wear of files intended for general purposes, consideration should be given to the kind of material to which they may be subjected in the different stages of their use. In the ordinary use of the machine [illegible] first wear of these files should be in finishing the larger surfaces of cast iron, bronze or grass metals, all of which require a keen cutting tooth; they may then be made to do good execution upon the narrower surfaces of these metals, and also upon wrought iron and soft steel; as a file that has been used more or less upon this kind will not tear the surface of these metals and will consequently do more effective work. To obtain the best results, the file suited for general purposes is not so well adapted to filing brass or other similar soft metals as those whose teeth are arranged for this purpose. New files, particularly double cuts are severely worn down by use upon narrow surfaces, as the strain comes wholly upon a few teeth and frequently breaks them.

Preparing Work

The corners or thin edges of iron castings are very likely to become chilled and a thin scale or skin produced over the entire surface of the casting, caused by the hot metal coming in contact with the moist sand of the foundry moulds; this outer skin is usually much harder than the metal beneath it, and many times the thin edges or orners are chilled so as to be harder even than the file itself.

To overcome this hard scale the casting is usually pickled by the foundry before it is sent out—a process of washing the castings in acid and grinding or snagging the edges, or particularly hard parts.

However, the casting, even after being pickled, retains a certain amount of sand and hardness on its surface and this will dull the best file made. Use an old file to break off this scale and clean off the casting and then a good file may be used without danger of injury to it.

The necessity, therefore, of removing this scale and chilled surface becomes readily apparent, and all mechanics who give any consideration to the proper and economical use of the file will be careful to see that the scale and sand are first removed by pickling, and the surfaces which have become chilled by grinding, before applying the file.

When Oil Should Not be Used

All files, when they leave the factory, are covered with oil to prevent them from rusting. While this is not objectionable for many uses to which the file is put, there are cases where the oil should be thoroughly removed, as when the file is to be used in finishing the larger cast iron surfaces which are of a glassy nature; the principal difficulty being to make the file "bite," or keep sufficiently under the surface to prevent glazing; otherwise the action not only hardens or burnishes the surface operated upon, but dulls the extreme points of the teeth, thus working against the desired end in both particulars.

When Oil May be Used

Oil may, however, be used to good advantage on new files which are put immediately to work upon narrow fibrous metals of a harder nature; in such cases, it is not uncommon, with good workmen, to fill the teeth with oil and chalk.

Oil is also useful on fine files in the finishing of wrought iron or steel, as by its use, the teeth will not penetrate to the same degree and the disposition to "pin" and scratch the work is materiallf less than when used dry.

Cleaning the File

The dust and small particles removed from the material operated upon are always more or less liable to clog and fill the teeth. This tendency is especially aggravated when the file is used upon wood, horn, and such other materials as will, upon being mixed with the oil in the teeth become baked when dry and thus prevent the teeth from penetrating the work as well as giving them the appearance of being worn and tending to injure them by rust.

In removing oil from the teeth of a new file, a ready way is to rub chalk or charcoal across the teeth and brush thoroughly. By repeating the operation a few times, the oil will be entirely ab-

Grinding Engineer Wrenches At High Speed

Disc Grinding is an Important Production Factor—Finishing Twelve Surfaces on Cap Screw Heads Simultaneously—Large Engineers' Wrenches and Smaller Sizes Can be Ground by This Method

*By J. H. MOORE

In a former article on "Disc Grinding," appearing in Canadian Machinery, June 2nd, the single spindle type of grinder only was shown. In the present article we will depict three examples of work performed on the double spindle type of machine, also one example of vertical disc grinding. Other operations performed by the disc grinding process will be described, but not illustrated, as with the previous, and present photographs, readers will be well acquainted with the style of machines used. We are again indebted to Chas. H. Besly & Co., Chicagt, for the use of these illustrations.

It is often advantageous to grind a number of pieces simultaneously. In such cases, enough parts are ground at one time to use up the power of the grinder, or the size of the disc wheel. Take for example Fig. 1. This view depicts a double spindle machine grinding cap screw heads on 6 screws and on 12 surfaces simultaneously. The work is accomplished on a No. 26-18-inch machine, from hot bar stock, using common wooden holders as shown. The one operator, and a boy helper who loads the holder, produce the following results: of the square head 1-4 inch cap screws at the rate of 2100 per hour; 3-8 in. size., 1821 per hour, and so on in proportion, up to 970 per hour on the 3-4 in. size.

On hexagon head screws, 1,115 1-4 in. screws per hour were produced, and 510 of the 3-4 in. size. On the 1-4 in. size 9 screws were held in the holder, 5 in the case of the 3-4 in. size. In between these sizes the production and number of parts held, were in similar proportion. These figures give a good idea of such a machine's productive possibilities.

Fig. 2 illustrates a similar style machine grinding brass hexagon nuts, twenty being held at one time in the fixture. On this operation it is the usual practice to grind as many nuts simultaneously as the capacity of the machine will permit, and of course the more you hold at one time, the greater the production.

At Fig. 3 is shown a rather interesting piece of disc grinding. In this case the machine used is a wet ring wheel grinder equipped with a sliding table and special work holder. The two sides of the head of extra large engineer's wrenches are ground at this operation, and their proportionate size to that of the operator is readily apparent. Single end wrenches 24 inches long, weighing 12 1-2 pounds each, with a 3 9-16 inch milled opening, are ground at the rate of 60 wrenches, or 120 surfaces per hour. Single end wrenches 44 inches long, 53 pounds weight, with 4 5-8 inch milled openings are ground at the rate of 12 wrenches, or 24 sides per hour. The small double end wrenches, shown resting on the table alongside of machine, are ground free hand, using an ordinary stationary work rest between the grinding wheels. The production in the latter case is exceedingly rapid, running as high as 600 wrenches, or 1200 surfaces per hour, per operator.

Many other interesting operations are being performed throughout the country by means of disc grinding, and as can be readily understood it is well nigh impossible to show even a small proportion in photographic form. In the next few examples quoted we will consider work pictures only.

In a certain plant, they are producing by disc grinding thin brass cover plates up to 6 in. by 10 in. These pieces are ground at the rate of 60 per hour, this figure, including both roughing and finishing. The parts are held in a special floating workholder, and the above production time is for one operator only. As the machine accommodates two men, the production is of course doubled.

At another plant they are finishing cover castings for automobile transmissions at the rate of 100 per hour. On this work they use a 24 inch wide face ring wheel at one end, and a 30 inch disc wheel at the other. The ring wheel has a vitrified wheel that makes for speed and economy, while the disc wheel, with its cloth back abrasive disc, gives the part the desired accuracy. Very simple workholders are used; three studs projecting from an ordinary angle plate forming a three-point bearing on the work. The piece is accurately located on this bearing by means of four heavy studs projecting from the face of the

Fig. 3.—Grinding a large engineers' wrench.

angle plate. It will be noted that no time is used up in rigid chucking—The work floating against the grinding wheel. The production figure given above includes both roughing and finishing.

All disc grinding is not confined to flat surfaces, for in another plant they are grinding the circumference of friction draft gear shoes at the rate of 60 per hour. The pieces are made from cast steel, and the area of each surface is 50 square inches. The work is clamped into a chuck which swivels on a central stud; while the workholder is mounted on a geared lever feed table. The circle used is what is known as No. 16 Boxite, and a 26-in. machine is employed. These pieces are accurately held to a given radius.

Another operation, employing both the ring and disc wheel, is the grinding of pillow blocks and caps; the production in one particular plant being 90 rough and finished ground caps per hour, and 30 pillow blocks in the same time; the bottom of these blocks being 6 inches by 13 inches. The castings are recessed in molding to facilitate grinding, and are kept closely to both flat surface, and accurate height. The former planer time on this job was 3 minutes each.

It always pays to see if you can improve on the present method of manufacture. For example, a certain plant was producing iron castings for door locks, and the method employed was the use of two milling machines with one operator, five surfaces being produced per minute. After disc grinding was adopted the production soared to 10 pieces per minute, and a finer and more accurate finish was secured.

Wet Ring Grinders

Here are several production times on wet ring grinders. In one plant the grinding of hardened square blocks for pipe tongs, is accomplished at the rate of 240 pieces, 4 sides, or 960 surfaces in all, per hour. Three pieces are ground at a time.

Another plant finds that the wet grinder does good work in rough grinding piston rings. An automatic grinding fixture is used, and as high as 15,000 rings have been completed in ten hours. The rings are ground to within .0015 in. plus or minus of size, and within .001 in. of parallel. The Besly Co., commenting on this work, state as follows. "The proper speed is about 900 r. p. m., with right hand wheel running down and left hand wheel running up. The right hand wheel should run 45 to 50 r. p. m. faster than the left hand wheel. This will cause a slight spinning of the ring and help to keep it parallel. The castings should be within .015 inch of finished size, and not more than .010 in. should be removed at one cut. If the castings are hard and of wide face, a slower speed is better. All bumps and projections should be removed before grinding, and plenty of water should be used. A wheel of rather coarse grain and soft texture is best for such work."

The vertical spindle disc grinder also has a wide range. In one shop cast iron flasks, 22 inches by 38 inches, weighing 165 lbs. each, are ground in 10 minutes, whereas the former planer method produced only 6 every 10 hours.

The pattern shop must not be forgotten, for in many plants disc grinding machines specially adapted to pattern-making, and general woodworking have reduced expenses, increased the output, and given a greater degree of accuracy. On pattern work it is often possible to get the apprentice to do as good work as the most skilled workman, as he has a mechanical means of producing an even surface.

Cheaper pattern lumber can be worked, as these machines grind hard wood or soft wood equally well, cross grains, straight grains, knots, shakes, and even nails or screws which may protrude to the ground surface. Work which was considered trimmer work can be done quicker and better, and the grinder takes much of the turning and smaller machine planing, and a large portion of the hand work, such as sanding, planing, cornering and general hand-fitting and finishing. With such machines an ordinary workingman can make as good a glue joint as an expert, and the same applies to jointing split core boxes.

Referring once more to the vertical spindle type of grinder, or gravity feed grinder, as it is sometimes termed, Fig. 4 illustrates one of these machines in actual operation. On this style of grinder the work to be ground is laid on the face of the disc wheel, and grinds from a gravity feed. Where the work is too light to grind satisfactorily, the usual practice is to lay on additional weights to hold the work to the disc. In either event, it is seldom possible to get the same feeding pressure as you can with the lever feed on the horizontal type machine, therefore grinding by the vertical method generally takes more time than where the lever feed is used.

This accounts for the fact that the vertical type machine is used only on certain classes of work, such as jointing and flatting. It is especially suited where the work is too large or heavy to handle conveniently on the lever feed machines, or where a number of pieces can be ground simultaneously.

For example, in jointing cast iron split motor bearings by gravity feed it requires about ten minutes to clean up a surface. The same piece could be

WELDING AND CUTTING

Points to Watch in Welding of Cast Iron

Skill and Experience Are Necessary Owing to Brittleness of the Metal and Necessity of Using Flux to Reduce the Oxide—Shape—Mold or Dam Welding

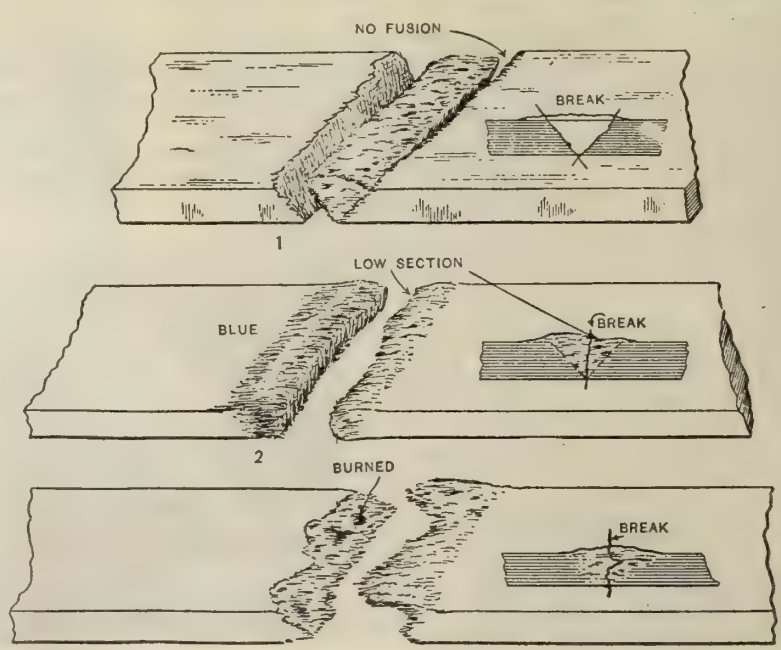
*By FRED L. ROGERS

THE welding of cast iron requires more experience and skill than welding steel, because of the brittleness of the metal, and the necessity of using flux to reduce and eliminate the oxide. Cast iron under the torch flame will not flow and blend until the oxide has been reduced by the action of a suitable flux. The molten metal appears "grainy" which betrays the pressure of oxide that must be eliminated by flux. The oxide of cast iron melts at a higher temperature than the iron itself, and hence cannot be ignored as in the case of steel.

The melting point of cast iron ranges from 1900 to 2300 degrees F., varying with the carbon content, the very soft iron containing as high as 2½ per cent. carbon melting at low temperatures, while the irons containing less carbon may require the higher temperature to fuse. The selection of welding rod for cast iron is highly important, more so perhaps than with some other metals because of the inferior characteristics of ordinary cast iron when used as welding rods. The use of an inferior grade of welding rod will produce hard spots and weak welds, and should in no case be tolerated.

Weight of Welding Rod Deposited Per Hour

When welding steel, using steel welding rod, the metal deposited will run from about 2¼ pounds per hour down to a few ounces depending, of course, on the size of tip and thickness of steel being welded. Welding ¾-inch steel plate at the rate of one foot per hour using a No. 9 d-b tip consumes about 2¼ pounds of welding rod per hour, whereas welding ½-inch steel at the rate of 1½ foot per hour consumes about 1⅛ pound of welding rod. Obviously, when welding say ¾-inch steel the consumption of welding rod decreases to a fraction of a pound. When welding cast iron, especially heavy sections, the amount of cast iron stick deposited may easily be as much as four or five pounds per hour, or more.



Use for Salvaging

What mechanic has not wished for a "putting-on tool" when he has turned a piece too small or has planed off too much by taking an injudicious depth of cut? The putting-on tool was a figment of the imagination and a practical joke until the oxy-acetylene torch came into use. It made the impossible not only possible but practicable.

It is now a not uncommon practice to salvage parts that have been spoiled by improper machining or that have been reduced by wear. Worn journals can be restored to the original diameters by welding a thin layer of steel to the surface. Of course, the welded metal on the journal must be turned and polished in a lathe before it can be used. There are many other machine parts that can be made whole again by building on adding material and machining to the required dimensions and finish.

One of the most frequent accidents to machinery is the breaking of gear teeth. A gear with a broken tooth is practically useless, and it may represent an investment of several hundred dollars. Ordinary methods of patching in a new tooth are mostly worthless as a patched tooth will have so little strength that it will be broken out as soon as an extra heavy load has to be transmitted. A tooth built up of adding material is as strong and durable as the original if properly done.

One of the interesting and unusual applications of the oxy-acetylene torch in this line is depositing a coating of cast iron on the seats of steel poppet valves used in gas engines. Cast iron resists the heat and abrasive action of exhaust gases better than steel. The cast iron forms a seat on the poppet valve equal to that in the cylinder casting, and out-

Characteristic defects in welded steel bars as shown by tensile test.

*From the author's book, "Welding and Cutting," published by the Davis-Bournonville Co., Jersey City, N.J.

lasts several steel seats, thus reducing the cost of up-keep. The cast iron coating of course must be accurately finished the same as the solid steel valve but being much more durable the cost is well repaid.

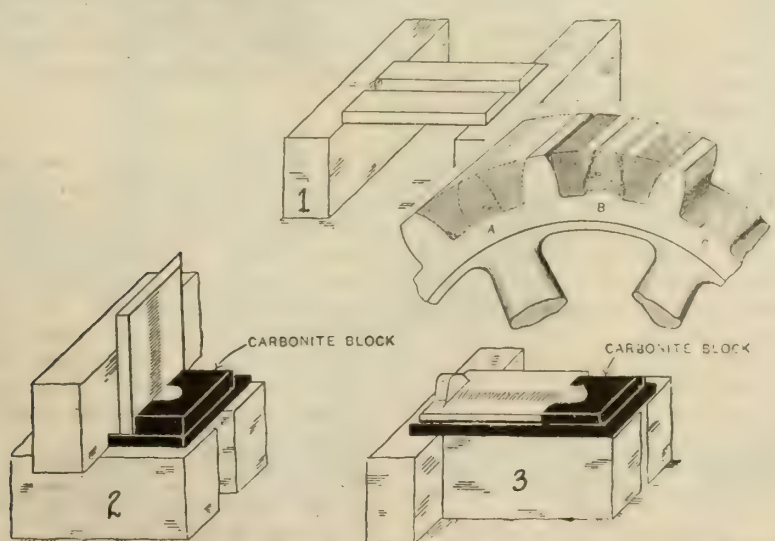
Shape Welding

There are two distinct kinds of shape welding, one being accomplished by torch manipulation alone and the other by the aid of dams and molds of high heat-resisting material. A boss can be built upon the face of a gray iron casting of any size and height by fusing on adding material in the quantity required. It is not difficult for the experienced welder to keep the margins from sloughing off or to control the shape or contour to simple forms. It is done by graduating the heat so that the molten metal at the edges is near the freezing temperature and flows only when the flame is held close. The moment it becomes too fluid the flame is whipped off and directed upon a colder part. The same manipulative skill is required as in finishing the end of a joint square. Less heat is applied than in the centre when finishing a joint and the torch is whipped up whenever the metal gives signs of breaking down and overflowing the edge.

Bosses can be built not only vertically but horizontally and at any intermediate angle at will. The usefulness of boss welding in repair work is obvious, and welders should practice it not only to acquire skill in forming bosses but to perfect themselves in the art of finishing welds square and in a workmanlike manner.

Mold or Dam Welding

When a new lug, ear or other part is required to replace one broken from a casting, it is generally advisable to make use of a mold or dam of some material like carbon blocks on carbonite which resist the heat of the torch flame and which can be readily cut, carved, sawed and drilled. Carbonite possesses these qualities in a most satisfactory degree, and is used generally for shape welding and also as a retaining wall for difficult side seam and vertical seam welding.



Suppose a lug has been broken from a casting and lost. To replace it is a matter of merely providing a carbonite mold of the shape required, open at the top and placing it against the casting with the opening opposite the break; the block is weighted down and the welder proceeds to fuse the face of the casting and supply adding material until the mold is filled to the required height. If the lug were not lost, it is often cheaper to build up a new one in a mold than to weld the old one in place. The preferable practice depends on the size and other conditions. Pre-heating the casting is advisable in order to prevent excessive expansion and contraction stresses, and the lug and casting should be covered with asbestos paper or other insulating material in order to prevent rapid cooling.

Carbonite Shapes

Carbonite is supplied in blocks or slabs, in various thicknesses from ⅜ inch to 1 inch, in width up to 6 inches, and in lengths of 36 inches. Rods of the same are furnished in diameters of ⅜ inch to 1 inch included. Carbonite rods are used to fill holes when welding radiating cracks. If properly placed, the walls will maintain their shape and thus render boring or reaming unnecessary. It will burn away slightly so that a little filing only will be required. In fact the judicious use of carbonite rods will often make welding feasible that otherwise would be impracticable on account of cost of subsequent machining.

Replacing Broken Gear Teeth

Broken gear teeth may be replaced successfully on all kinds of gray iron and steel gears but it is not advisable to attempt the replacement of the teeth of motor car transmission gears except as an emergency repair. These gears are generally made of alloy steel and specially heat-treated to give them toughness and durability, and unless the welded teeth are made of the same metal and heat-treated the job will not last. However, there are many other broken gears that can be repaired with uniform satisfaction.

Welding lugs to cast iron with aid of carbonite block. Restoring broken gear teeth with and without carbonite blocks.

The practice of replacing broken teeth depends on the gear and local conditions. A gray iron gear with cast teeth can be repaired by building up a new tooth alone, using carbonite blocks in the adjacent spaces to hold the new metal closely to the general thickness of the old tooth. Care must be taken in preheating not to crack the rim and the welded tooth must be protected from cooling down too rapidly when complete. When the welding is finished and the casting has cooled down the tooth is ground to shape with a portable emery grinder or chipped and filed to a templet.

If the gear has cut teeth and a gear cutter of sufficient capacity is available the preferable practice is to build in the broken teeth and adjacent tooth spaces solid with new metal, and then cut two spaces on the gear cutter. This should produce a solid well formed tooth. An alternative method less expensive but not so likely to produce a good job is to build in the tooth with carbonite blocks alongside, and finish with the gear cutter. The difficulty is that the cutter is at disadvantage in cutting, having to cut metal on one side only. Springing and chattering are bound to result making considerable hand finishing necessary.

Broken Pulleys

One of the difficult jobs that trouble the mill repair man is mending a broken cast iron pulley. This probably presents the most complex problem in expansion and contraction stresses that the welder ever meets. It is essential that the job run true when finished, and unless the piece is carefully treated and welded it may be far from true when finished. The chances are that the inexperienced welder will not only fail to secure a true job but he will usually break the pulley at another place.

Two conditions of broken pulley repair requiring quite different heating treatment will be found. The first case to be considered will be a broken spoke: The spoke should be chamfered or beveled the same as any other piece to be welded, and the rim should be preheated on each side of the spoke so that when the whole pulley is cooled there will be no internal stresses in the spoke or rim, and the rim will not be shrunk out of true. The degree of preheating and amount of expansion vary, of course, with the size of pulley, thickness of rim and spokes and other conditions.

Almost every case presents a new problem, and it is in handling such work that the experienced welder displays his skill and judgment. When the weld is completed the preheated and welded parts must be shielded from drafts, using asbestos sheets preferably for the purpose. The thickness of asbestos can be graduated so that the rim will cool at approximately the same rate as the spoke; the spoke usually will require more covering than the rim but not always.

When a pulley rim is broken between the spokes, preheating must be applied to the hub to throw the rim apart at the break. The joint should be beveled

both inside and outside. Again it is a case where the conditions will govern the practice and hardly two cases are alike. The same care must be taken to protect the welded joint and the hub when cooling down so as to equalize the contraction stresses and prevent fracture and distortion.

Welding Broken Gears

While the welder who is able to weld broken pulleys so that they require little truing up and stand up in service, is generally able to handle almost any job of cast iron welding that may come his way, he may be called on to weld broken gears that present even greater difficulties than broken pulleys. Generally speaking, a badly broken small gear is not worth welding, and the owner will save trouble and money by obtaining a new one. However, there are conditions arising where it seems absolutely imperative to weld a broken gear even though it is badly smashed and the actual cost of welding will be greater than a replacement. It is the time element that counts most in such cases.

For instance, in mills, factories and railway roundhouses there are special machines whose more or less constant operation is necessary to keep the business going. If a gear in such a machine breaks down it is necessary to replace or repair it immediately, and if no spare gear is available the welder will be put on his mettle to show what he can do. The procedure to be followed in such cases will vary of course with the size of gear and the fractures. If not more than four or five feet in diameter and if badly broken, the following is recommended:

Assemble the broken parts after having cleaned them thoroughly and line them up by the fractures as nearly as possible in the original relations. Make an iron band and shrink it on the rim so as to hold the parts true and firmly in position. If the gear has been broken through the hub these breaks should be beveled before assembling but the other breaks should not be beveled as the fracture surfaces intact will be required to line the pieces up. Having shrunk the band in place preheat the gear in a furnace to low red and weld the hub. Next, burn out the breaks on one side to a depth nearly equal to one half the thickness, and weld. Burning out breaks in cast iron is expensive in time and gas but for emergency work of this sort it is profitable inasmuch as the orginal fractures are required to line the parts up accurately. Having burned out and welded the breaks on one side the gear should be turned over and reheated for burning out and welding the breaks on the opposite side.

It will be noted that welding a broken gear as described is done with the parts held in place by the band which is shrunk on the outside. Care must be taken to prevent the band being overheated when preheating the gear. The effort should be to keep it tight and to prevent it becoming so hot as to give or stretch and thus loosen the grip.

TO GET THE BEST OUT OF A FILE

(Continued from page 23)

sorbed and the file will be in the best possible condition for use upon cast iron.

When the teeth of files are clogged with wood, or other soft substances which has become baked into them, if the file is held in boiling hot water for a few moments, the imbedded substance becomes so loosened that it may easily be carded out of the teeth. If the operation be quickly performed, any moisture remaining will be readily evaporated by the heat retained in the file.

This cleaning is done in several ways: sometimes, in the finer files, by rubbing the hand over them or by drawing them across the apron of the workman; in others, by striking their edge upon the bench or vise; and again, (which is a more common method with the large files), by the use of a strip of old or worn out card clothing, tacked to a piece of wood having a handle shape at one end—a device which is usually rudely constructed by the operator.

The file should be cleaned not only at intervals during its use, but carefully before being laid aside, if the best results are to be attained.

The File Card and File Brush will be found excellent tools, and master mechanics should see that every file-user in their employ is furnished with one or the other of these, and insist that they be used, if they wish to economize in the wear of their files.

Metals like copper, or brass with high alloy of copper, require a very sharp keen file, preferably of specially shaped teeth, just as these metals require a sharp pointed, keener lathe or planer tool. Special work may require a special file, but stock shapes and cuts will usually be found to meet nearly all requirements.

Care in Putting Away

One of the most destructive customs is that of loosely throwing files, fine and coarse, small and large, into a drawer filled with cold chisels, hammers, turning tools, etc., and then throwing the chisels, hammers and other tools on to the files.

When we consider how small a portion of the points of the teeth is worn off by extreme wear when the file is properly used and that to effectually dull them for some kinds of work requires but slight knocking upon a hard substance, it will be easily seen that the evils of this habit should be more carefully considered by the master mechanic, and suitable provision made to avoid its destructive tendencies.

Summarizing the various hints we have the following:—

Select the proper shape and cut of file for the work.

Handle properly.

Have work properly secured and at a convenient height.

Hold file in a manner to give best control.

Keep pressure on file sufficient to keep it cutting—less for a new file—more as it becomes dulled—but keep it cutting.

Keep file clean—a dirty file is a dull file.

Clean surface of work to be filed.

Take good care of your files. Don't abuse them. They are cutting tools.

GRINDING ENGINEERS' WRENCHES

(Continued from page 24)

ground by lever feed in half a minute, but the vertical type machine does it cheaper because 35 pieces can be ground simultaneously, and a laborer can be used to put the work on and off the grinding wheel. Thus the decision becomes largely one for the production engineer, and he must weigh carefully the two methods, before deciding which is the best for the plant to use.

Take as a typical case the grinding of cast iron bed plates for power pumps. These castings were 33 inches wide, by 38 inches long, and weighed 115 pounds each. The total ground surface totalled 100 square inches, and by using the vertical style grinder, the planer time was increased ten times the former figure.

In the example shown at Fig. 4, cast iron gear cases are being surfaced. These cases are 18 inches long, 13 inches wide, and are ground from the rough. They must be perfectly flat for an oil tight joint, yet they are completed in four minutes each. This excels the former planer by 36 minutes.

As previously stated, one could go on indefinitely telling of work performed by the disc grinding process, but we shall leave the subject at the point until some later issue.

FACTS THAT COUNT

Canadians who want to know about their vast country and its resources should secure a copy of a little booklet which the Natural Resources Intelligence Branch of the Department of the Interior has recently issued. "Compact Facts," as it is called, contains in concise form a useful variety of information regarding the Dominion, its extent, capital invested, wages paid, value of live stock, mineral resources, production, etc. Copies are available on application to the Department at Ottawa.

ERRATA

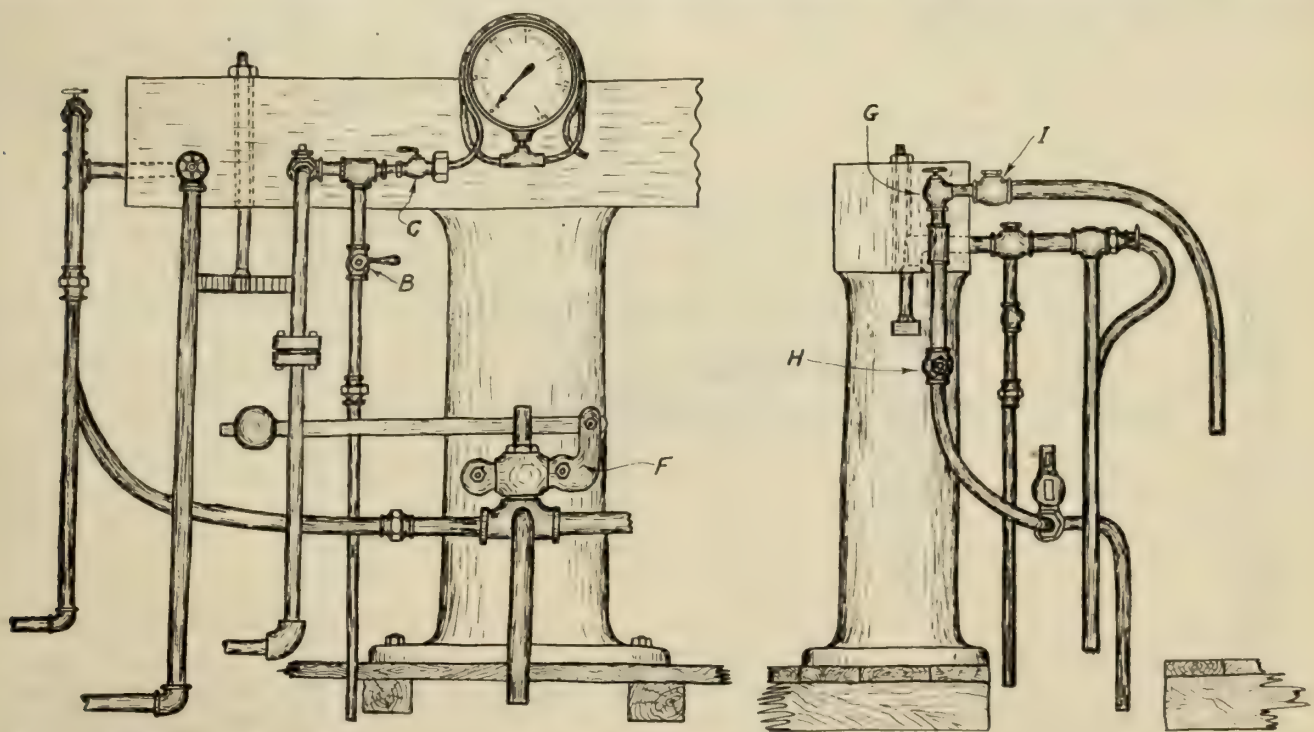
In the special article, in the annual review number of Canadian Machinery, dealing with the automobile industry, the words "total production" appeared over a table of statistics when they should have been "total registrations." Also the figure (I) was set where an (0) should have been, so that a sentence reading that the total number of cars registered in Canada in 1913 was 220, should have stated that the total registered in 1903 was 220.

On page 138 of the special issue appeared a table headed "Census of Knit Goods." This should have read "Census Figures of Woollen Textiles."

WHAT OUR READERS THINK AND DO

Testing of Locomotive Superheater Units

THE USUAL method of testing superheater units by means of the cold water pressure method is to use a pump to obtain the necessary pressure. However, in the Grand Trunk Railway Shops at Point St. Charles, Montreal, a clever apparatus for testing these units has been constructed whereby the pressure is obtained from the regular high pressure hydraulic lines of the shops. This does away with the necessity of a special pump. Two other outstanding advantages are the facts that the work is accomplished in perfectly dry surroundings, and that the water is completely expelled from the units into a pit at the conclusion of the test, which is accomplished in a remarkably short time.



The sequence of operations, perhaps, would be the best method of describing the apparatus and its method of functioning. First the unit is clamped by one "T" headed bolt to one side of a "T" casting which takes the place of the superheater header in actual service. The 45 degrees bevel seat in the casting fits the spherically ground end of the unit. The outer end of the unit is supported on a special adjustable stand.

It might be well to mention here that the apparatus is of a dual nature. There are two sets of seats for units to be tested. While a unit is being removed and another one attached to one side, testing operations are being carried on, on the other side of the apparatus.

As soon as a unit is clamped in position, a valve "A" (Fig. 3) is opened that lets city water into the unit. At the same time the lever valve "B" (Fig. 1.) is opened which permits the air to be expelled from the unit. (It will be noted that water entering one arm of the unit through valve "A" expells air through the opposite side of the unit.) To this latter valve an overflow pipe is attached leading down into a pit below the floor, but the end of this pipe is at the same time in open sight, as will be seen in Figs. 1 and 2. When the unit is filled with water a solid water discharge from this overflow is seen. Then the valve "B" in the overflow line is closed. Immediately the full city pressure is conveyed to the unit, the lever valve "C" (Fig. 1.) is then opened and its corresponding valve on the opposite side of the apparatus is closed. The gauge now registers the pressure in the unit as supplied by the city mains. Following this the city pressure is cut off by closing valve "A".

The gauge is connected to a "T" from which two leads run, one to each side of the apparatus. In each of these two lines of 5-16 inch copper tubing, a small lever operated valve is placed to enable the gauge to indicate pressures on either side of the testing apparatus. Between the ¾ inch city pressure supply line valve "A" and the header casting is a high pressure brass check valve, "D" (Fig. 3.) also the nipple between the check valve and the header is made from high pressure piping. This check valve "D" is to prevent injury to the low pressure lines in the event of the operator carelessly leaving the valve "A" open. It also prevents any wasting of water from the high pressure lines.

The gauge as before mentioned, indicates the pressure in the unit at the time the city supply is cut off. Next, the high pressure valve "E" (Fig.3.) is opened with a detachable handle which fits on the square extension of the valve stem, and water from this line at a pressure of 1,500 pounds per square inch is introduced into the unit through an opening 1-8 of an inch in diameter. The gauge slowly climbs until a pressure of

Figs. 1 and 2, showing both the side and end view.

from 250 pounds to 275 pounds per square inch is indicated. At a predetermined point the weighted relief valve "F" (Fig. 1) is set to open. Discharge from this valve goes into the pit, as shown in Fig. 1. Then the unit is examined all over for leaks. Next the high pressure water is shut off and the overflow valve "B" (Fig. 1.) opened. Following this compressed air is forced into the unit by opening valve "G" (Fig. 2.) ejecting all the water into the pit below.

The unit is then removed, and another inserted. Should a leak develop a welding outfit is used to weld the pipe on the spot and again the pipe is tested. The relief valve is connected to both sides of the apparatus, and by means of two valves it can be placed in the line of the side in use. One of these valves is shown at "H" (Fig. 2.) They are operated by the same detachable crank as operates the valve "E."

Check valves are also provided in the air line so that no water can accidentally be admitted to the air lines. One of these check valves is shown at "I". (Fig. 2.) Each side of the apparatus is provided with separate and independent air, high and low pressure water, and overflow lines, with independent operating valves. The gauge and relief valves only, are common to both sides. They are thrown over from one side to the other by means of valves as shown.

The high pressure line delivering water to the unit is ½ inch high pressure pipe. That is to say it takes ½ inch fittings but the actual inside diameter of the pipe is about 5-16 of an inch. The lines leading to the relief valve are also ½ inch high pressure pipe. This permits of ample protection as the high pressure intake opening has been reduced to a diameter of ⅛ of an inch. Regarding this, it may be stated that a much smaller intake opening would be sufficient, but when using a smaller opening, say 1-32 of an inch, or 1-16 of an inch, difficulty is encountered with small bits of foreign matter in the water, clogging the opening.

The air line is ½ inch standard pipe, and the overflow line from valve "F" is ¾ inch pipe. Originally the seats in the "T" shaped header casting were spherical, in order that they fit the spherically ground ends of the units. These seats sometimes leaked and it was found that a 45 degree bevel seat, giving line contact gave practically perfect results.

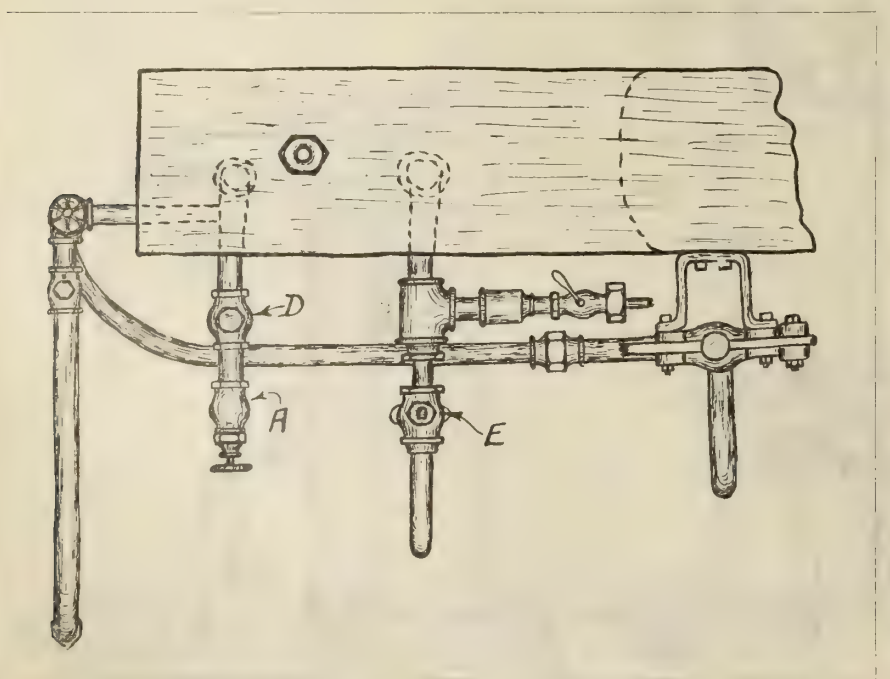


Fig. 3—A Plan View of the Apparatus.

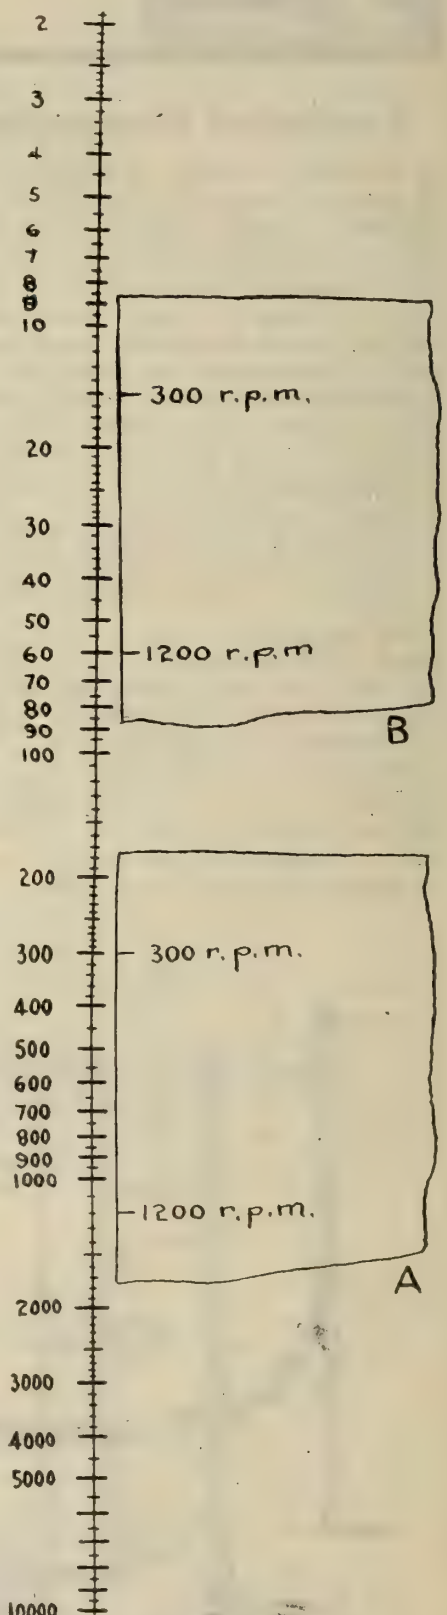
QUICK PULLEY COMPUTATIONS

By W. F. Schaphoist



(All Rights Reserved)

The simple chart shown does away with formulas for making pulley computations. It will be found to be exceedingly quick. Just slide the slip of paper from position "A" to position "B" and the problem is immediately solved.

For example:—A motor running 1200 r.p.m. is to drive a line shaft at 300 r.p.m. What sizes of pulleys should be used? On the slip of paper in portion "A" make marks opposite the 300 and the 1200 as I have done. That's all you need do; but if you want to write down "300 r.p.m." and "1,200 r.p.m." also, all right—it doesn't make any difference.

Then slide the slip of paper up to wherever you want it. Position "B" shows that pulleys 15 inches and 60 inches in diameter respectively will do the work very well.

If those diameters are considered too large just shove the slip a little higher and choose the best diameter. No matter where the slip is placed, the ratio is always correct—no figuring is necessary. The chart also lends itself readily to the solution of such a problem as —knowing the pulley diameters, and knowing the speed of one of the pulleys, what is the speed of the other pulley?

This chart could well be clipped out and pasted to a piece of cardboard for general use.

Recent Developments in Mechanical World

Stainless Steel For Turbine Blades

STAINLESS steel, which was discovered in the research laboratory of a British steel works, has been developed recently in quite a number of engineering directions. One of the most successful is in connection with the blades of steam turbines. Hitherto these blades have been made of 5 per cent. nickel steel, which was the best known substance for the purpose. Nickel steel, however, was found to corrode and wear away under the action of the steam, and it occurred to the inventors of stainless steel that it would be worth while trying whether the new material would stand up better than nickel steel. Accordingly several stainless steel blades, together with some new nickel steel blades, were inserted in a steam turbine more than a year ago. When the turbine was again opened recently the stainless steel blades were found as clean and smooth as on the day they had been inserted, while the nickel blades were deeply pitted and their edges badly worn away. A British electrical engineering firm made a similar experiment for a longer period with the same result. As the pitting of turbine blades reduces the efficiency of the machine and involves costly replacement, it is practically certain that stainless steel will supplant nickel steel for this purpose. Apart from engineering uses, the most popular new application for stainless steel appears to be in connection with golf clubs. For this purpose stainless steel is ideal. Other familiar uses include mirrors, fenders, fire irons, knives, scissors and surgical instruments.

The Production Of Liquid Air

THE essentials of a plant producing liquid air by the Hampson process are the compressor, purifying train and liquefier. The compressor, usually of four stages, delivers air at room temperature and approximately 3,000 pounds per square inch. The compressed air purifying train consists of first, a trap for receiving oil and water, and secondly, suitable containers which are charged with chemical reagents, such as sodium hydroxide, calcium chloride, or lime, for removing carbon dioxide and water vapor. The air thus compressed and purified, says Scientific American, is delivered to the liquefier, in which, after passing through a coil of copper tubing, the air is allowed to expand freely to approximately atmospheric pressure. Where this drop in the pressure takes place there is a corresponding drop in the temperature of the air. The expanded air, before leaving the liquefier, is caused to circulate around the copper coil which contains the compressed air, thus cooling the coil and, in turn, the compressed air so that on continuous operation a cycle of progressive cooling is maintained until the temperature ultimately reaches the liquefying point. The liquefier is so constructed that the air which is condensed to liquid is delivered into a receiving vessel. The gaseous air exhausted from the liquefier is returned to the intake of the compressor for succeeding cycles because it has been purified, and when used repeatedly will be less exhausting on the purifying reagents. For laboratory production of liquid air this process leaves little to be desired.

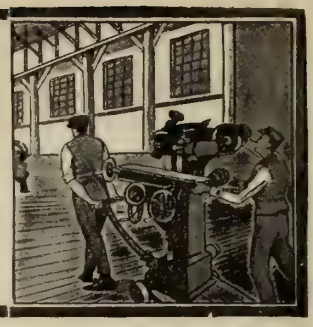
New Oil-Gas Burner

A DEMONTRATION was given in London, England, of a new type of burner for use with oil. The oil is first converted into gas in a chamber filled with nickel gauze heated by the flame. The oil gas then passes through a regulating valve and issues as a jet which carries with it the air required for combustion. The mixture then passes into another chamber, where it is still further heated; and it issues from orifices arranged according to the services required. No carbon forms in the burner, and it does not require cleaning. This invention is said to be adaptable either for heating or lighting in conjunction with an incandescent mantle.

Important Coal Deposits

FROM a report to the dept. of Overseas Trade, we find that the most important coal deposits in Mexico are at Sabinos and Coahuila, and are estimated to cover about 400 square miles. The coal is of a good coking quality. About 1,000,000 tons per annum were mined before the revolution, but the output has now fallen to about half. All the coal produced is used in the country, the bulk of it being consumed on the plateau; foreign coal is imported on the coast. The coal reserved in the country is estimated at about 100,000,000 tons.

The Marvels of Aluminum



SINCE aluminum was produced in a commercial form the greatest interest has been taken in its application to various engineering structures where lightness with strength is desirable. It was soon found that when aluminum was alloyed with other metals its strength was greatly increased without any great change in weight. Various alloys of aluminum have been used in the structure of airships and aeroplanes, and the results have been so promising that a special committee was formed in Great Britain to undertake systematic research of the properties of aluminum alloys. A report recently issued by this committee embodies the results of seven years of research conducted in the National Physical Laboratory, which is subsidised by the British Government. This research has resulted in the discovery of many alloys which are of great promise for practically all kinds of engineering, particularly automobile manufacture, railway rolling stock, internal combustion engines and steam engineering. The only problem awaiting solution is the production of these alloys on a commercial scale. Already a beginning has been made in this direction by a British Government factory; and manufacturers are looking closely into the possibility of producing some of these substances for regular use in place of steel.

Smokeless Fuel

FOR YEARS a number of inventors in Great Britain and elsewhere have been trying to solve the problem of producing from coal a smokeless fuel which can be satisfactorily burnt in the ordinary open grate. The method adopted is to distil the coal at a lower temperature than is used in the ordinary gas works. When this is done, gas is produced together with valuable oils and other by-products, leaving a material which is roughly midway between coal and ordinary coke in composition. Many difficulties were encountered in the attempt to make this process mechanically good and commercially sound. These difficulties seem to have been overcome in a large installation now at work in Great Britain, capable of treating about 36 tons of coal per day. The fuel produced is hard enough to withstand ordinary transport and it burns brightly in a grate, giving off a large mass of radiant heat, and showing no trace of smoke. The success of this installation depends mainly upon an ingenious arrangement of the retorts. When coal is distilled at the low temperature mentioned it expands, and this expansion in the retort is apt to make the resulting coke very friable. In the new installation, however, the retort is fitted with a double internal partition; and as the coke expands the two parts of the partition are brought together giving room for the expansion and enabling the coke to retain a firm structure.

DEVELOPMENTS IN SHOP EQUIPMENT

PORTABLE PNEUMATIC TURBINE GRINDER ATTACHMENTS

The small pneumatic turbine recently placed on the market by the Onsrud Machine Works of Chicago, Ill., and described in these columns, has been fitted with two interesting attachments. One of these attachments makes a bench grinder of the machine, and it is thus capable of handling a large variety of light grinding. The other attachment makes the turbine grinder suitable for the accurate grinding of 60 degree centres. A detachable plug is inserted in the spindle of the tail stock of a lathe or other machine, and a bracket mounted on this plug holds the grinding wheel at the proper angle so when the tail stock is advanced on the centre the latter will be correctly ground. The tail stock plugs make the attachment applicable to both large and small machines.

NAMEPLATE "DRIVE-SCREW

The Parker Supply Co., of New York City, have recently placed on the market a "drive-screw" which was designed to present an easy and inexpensive method of permanently attaching nameplates, trademark plates, etc., to machine tools and other articles. The screw has a round head but is not slotted. The threads have a very coarse lead and the shank is somewhat smaller in diameter than the root diameter of the thread, for a short distance beyond the threaded portion. This cylindrical pilot is inserted in a hole slightly larger than diameter drilled in a machine to which it is desired to attach a nameplate. It is simply necessary then to strike the screws a blow with the hammer. These screws are hardened and heat-treated and the threads readily cut their way into iron castings, and as the heads are not slotted the screws are not easily removed by any person desiring to substitute another nameplate.

DOUBLE-HEAD HOLE GRINDING MACHINE

The Bryant Chucking Grinder Co., Springfield, Vt., have recently designed a hole grinding machine that is somewhat of a departure from standard practice, in that it carries two heads, one on the left hand, and one on the right hand end of the frame, also a chuck centrally located between the two heads. The machine was designed primarily for grinding piston pin holes in gas engine pistons. It is said to cut the time of this operation in two. The spindles through a special feed mechanism, can be arranged so that they will be fed automatically in the same direction, or in opposite directions. Holes can be ground from each end, cutting the time almost in half and avoiding excessive overhanging of the spindle which is the principal cause of bell-mouthing. A special diamond wheel trueing device is mounted on the machine as regular equipment so that finishing cuts can be taken while using both spindles. There are many innovations in connection with the feed mechanism which permits of a wide range of application to accommodate work of a diversified nature.

The machine weighs about 2,300 pounds and occupies a floor space of 3 feet by 6 feet. Pistons up to 4½ in. diameter and 4½ in. long can be accommodated. The tool is regularly supplied with a countershaft drive, but if an independent drive is required a 3 h.p. 1,720 r.p.m. motor is recommended. The standard equipment includes two standard internal wheel heads, an assortment of wheels, diamond and holder, countershaft and necessary wrenches.

GARAGE STAND

The Western Tool and Mfg. Co., Springfield, Ohio, have recently placed on the market a three-deck garage stand, under the name of "Champion." The bottom and top decks of the stand are trays for tools, the middle deck contains a number of pockets for small pieces, such as nuts, bolts, screws, etc. The three decks are substantially held together by means of a pipe frame. On the top deck is mounted one of the company's vises. Underneath the top deck is a drawer provided with a hasp and lock in which tools can be placed. A brake is provided, which can be easily operated by means of a lever located under the vise. When locked the brake prevents movement of two of the four casters on which the stand is mounted, thus providing a substantial work-bench. The height of the stand is 39 inches, the length of the top shelf is 42 inches and the length of the middle and bottom shelves is 43 inches. The width of the top shelf is 14 inches. The middle and bottom shelves are 26 inches wide. The drawer is 14 x 14 x 4½ inches.

MARKING MACHINES

A machine for rolling names and patent marks on small tubing has recently been brought out by the Noble and Westbrook Manufacturing Co., Hartford, Conn. The machine is power driven through a three-step cone pulley, the final delivery being through a worm and worm gear. The machine is equipped with a round revolving table mounted in a horizontal plane. This table is divided into six equal parts, each having a vertical mandrel upon which the work is fed by hand. As the table revolves it passes the work over the die and makes the mark. A cam next raises a lever, ejecting automatically the work from the machine. The operator has only to feed the work on the mandrels. A production of 10,000 pieces per day has been estimated. The machine will mark short lengths of any size pipe, and its weight is about 90 pounds.

ELECTRIC PORTABLE DRILL

The Black and Decker Co., Baltimore, Md., recently announced the development of an additional electric drill to their line of portable machines. The new drill has an aluminum alloy housing, and is provided with a universal motor which operates on either direct or alternating current at 110 volts. Motors which operate on 32 volts or 220 volts can be supplied on special orders. A die cast aluminum alloy fan is keyed to the armature shaft thus providing ample air for cooling the motor. Double-reduction, stub-tooth, heat-treated, chrome nickel steel gears, running in grease, are provided. The control is by means of a pistol grip and trigger switch. The chuck is of the three-jaw, geared-nut type for straight shank drills up to ½ inch in diameter. The net weight of the drill is 15 pounds. Standard equipment supplied includes 14 feet duplex electric cable, attachment plug, combination spade handle and breast plate and detachable side handle.

The terminal connections are fully protected, but by removing two screws a cover plate can be lifted off exposing these connections. Thus a cable can be quickly renewed. This drill fits the B & D post drill stand this enabling the machine to be converted into a bench drill very quickly.

VERTICAL SPINDLE SURFACE GRINDER

The Badger Tool Co., Beloit, Wis., have recently placed on the market a large type of disc grinder, of the vertical spindle type. The disc wheel is 42 inches in diameter, being made of steel, and completely faced with a special abrasive compound ½ inch in thickness. This compound is moulded directly on the steel disc wheel. The machine is direct motor driven, the motor shaft serving as the spindle. Special rigid dust proof end yokes are provided, also forced lubrication, radial and thrust ball bearings. A twenty horse power motor with a speed of 600 r.p.m. forms the regular equipment. A circular dust channel completely surrounds the periphery of the wheel and terminates in two openings to which the dust exhaust system is attached. This exhaust channel is completely exposed by removing the outside guard ring which forms the top wall of the dust channel.

Stop bars are attached to the guard ring to prevent work from revolving with the disc wheel. The machine is accessible from all sides so that when small parts are being ground, several operators can work at the same time. The weight is about 3,800 lbs. A chain hoist helps to speed up production.

ELECTRIC HOIST

The Shepard Electric Crane and Hoist Co., of Montour Falls, N. Y. have recently placed on the market an electric hoist. The crane is designed to operate on an overhead runway and can be easily attached to a standard "I" section of the proper size. A fully enclosed motor is furnished with interchangeable frames for direct and alternating current. The motor was especially designed and developed for hoist work, it being carefully insulated and impregnated to protect it from moisture.

The direct current motor is of the standard, series wound, interpole type. The no load speed is twice that of the full load speed, so that a light hook is handled twice as quickly as a full load. The induction motor furnished for alternating current may be either the squirrel-cage or the slip-ring type. The squirrel-cage motor is used with the single speed control and the slip ring type with the variable speed control. As just mentioned, single speed and variable speed controllers can be furnished for either type of motor. The direct current variable speed controller gives from eleven to thirteen speed changes according to the size of the motor. When alternating current is used eight running speeds are available. The controllers, like the motors, are readily accessible although fully enclosed and well protected against dust and moisture. All parts of the mechanism, including the resistance, can be removed without disconnecting a single wire. The contacts and brushes can also be removed without disturbing other parts of the controller. A mechanical brake of the multiple disc type is provided, the function of which is to automatically hold the load when the motor is at rest. It also prevents excessive speed when lowering. An electric brake of the multiple disc type brings the motor promptly to rest when the current is cut off intentionally or otherwise. An automatic limit switch prevents overrunning of the load hook.

NUT CHAMFERING MACHINE

The William H. Haskell Mfg. Co., of Pawtucket, R. I. have recently developed and placed on the market a machine for chamfering cold-punched square and hexagonal nuts from ¾ to 2 inches. The machine is made in two sizes. The nuts are placed in a chute at the front of the machine from which a feed-finger takes them, one at a time, and places them on a hardened steel die. While on this die they are chamfered and then ejected into a truck or other receptacle.

COMBINATION VISE, DRILL JIG AND MILLING FIXTURE

The W. B. U. Tool Co. of Worcester, Mass., have recently brought out a combination vise, drill jig and milling fixture which is designed to hold work with accuracy. The vise is designed to hold work on which two or more cuts are to be taken at different angles and such operations can be accomplished without resetting the work. Adjustments to the jaw as well as to the swivel base are provided and graduations throughout the whole 360 degrees are also available. The equipment is especially suited for use on those machines where work can be tested with a square directly from the work-table. The equipment is provided with a solid drill bushing plate having eighteen holes ranging from 7-64 of an inch to 3-8 of an inch in diameter. Round, square or flat stock can be accommodated in the vise by "V" blocks or other special plates to accommodate the above mentioned shapes. Round stock from 5-16 to 1 inch in diameter can be accommodated. Screw adjustments are provided throughout. When the vise is used for filing operations it is unnecessary for a toolmaker to remove the work frequently in order to ascertain whether it is being filed square, as reference can be made directly from the plane surface, on which the vise may be placed.

SCREW-BLADE PROPELLER BLOWER

The Coppus Engineering & Equipment Company of Worcester, Mass., have recently placed on the market a screw-blade propeller blower, suitable for a variety of applications. It is being marketed under the trade name of "Vano". The blower is equipped with an air turbine dryer or can be driven by means of an electric motor. The air is delivered from the blower in the same direction as that in which it enters. The principal feature is a stationary guide vane beyond the propeller which has individual blades that radially sub-divide, without shock, the air currents leaving the propeller. These blades, which have a curvature that increases in the direction of the propeller rotation, concentrate the air current and give it a further acceleration inside the stationary guide vane, so that a considerable portion of the pressure is produced in the latter. A large part of the end thrust is thus taken up by the stationary guide vane casing. The air streams into which the flow of air is subdivided by the blades rotate slightly as they leave the guide vane casing, and converge toward the axis so that the smallest section of the air flow is beyond the casing.

COMBINED WORM AND SPUR-GEAR SPEED TRANSFORMER

The Nistisch Gear Works of Brooklyn, N. Y. have recently placed on the market a speed transformer which by changing the ratios of the gearing speed reductions ranging from 75-1 to 600-1 can be accomplished. The case is of cast iron and is oil tight and rust proof. The application of this speed transformer is said to be very wide.

MOTOR-DRIVEN BLOWER UNIT

The Chicago Flexible Shaft Co., Chicago, Ill., have combined the Stewart positive-pressure blower with a motor on a common base-plate to supply an apparatus which will serve a heat-treating furnace independently of the main power plant. The application of the apparatus is where it is desired to run a heat-treating furnace without starting up the main plant. It is also particularly adaptable for installations in remote quarters. Four regular sizes are manufactured which accommodate blowers Nos. 3 to 6 with motors varying in power from 1 to 2½ horsepower. The motors for the standard equipment are supplied in varying types to accommodate various conditions.

A NEAT GAS ENGINE ACCESSORY

It often happens that when the spark apparatus of a gas engine fails the magneto is alleged to be at fault, whereas the trouble is due really to imperfect insulation. A British firm has brought out a simple appliance for testing the insulation without dismantling. This appliance consists of a handle carrying a stem on which an insulated plug and a pivoted lever are united by means of simple connections. The magneto may be tested for spark and the pole-piece for leakage.

The Value Of Courtesy

AMONG the entries which should appear on the credit side of every business firm's ledger is the word courtesy. It is an asset and may be capitalized.

With the keen competition which modern conditions and methods have brought about has come a public temperament of quick and keen impression. It is susceptible to politeness, to attentiveness and to finesse of manner, the abrupt, indifferent or churlish person has no place except at the tail end of the line. Even there his legs will eventually prove too weak to carry him far.

Courtesy is an intangible factor. Its value cannot be easily measured or appraised, but it is just as essential in the factory, shop, office or wareroom as is quality in steel. Men who rise to responsible executive positions early learn its importance. They also develop its power and are constantly appreciative of the employee who displays the virtue which lifts a man above his fellows.

One of the first attributes of a boy entering an office with the hope of securing a position, is courtesy. The word should be written on the face of every traveler as distinctly as his name is printed on a calling card. Presidents and general managers generally realize its meaning long before they rise to places of trust. The higher they get and the wider their experience, the more they employ it in relation to the highest or lowest around them.

What big men have found it wise to do, smaller men should consider it worth while to try.

The File Is a Cutting Tool

ON ANOTHER page of the present issue will be found an article containing various hints and suggestions regarding "Filing." Mechanics as a rule are apt to look upon a file as something which can be used a few times, thrown away, and another secured. They give little thought to the cost, feeling that—well, the management pays for them.

The result is, that the manufacturer views with alarm the number of files purchased every year; makes up his mind the brand used is of poor quality, and switches over his trade. If he does not do this, he at least refuses to purchase more than a certain number every year, with the result that the workman himself, as well as the maker of the file, suffers.

If the manufacturer turns his trade over to someone else, the file maker is the loser, for his product may be equally as good, if not better, than the new ones purchased, but the workers have not been giving them a fair chance. On the other hand, should the number of files ordered be reduced, the efficiency of the worker drops. The task of working with a blunt file is irksome, so that the temper of the employee is also to be reckoned with. All these troubles can be avoided if the mechanic will only take to heart the suggestions contained in the article in this issue, together with the portion which appeared last week.

A splendid point brought out in the article is the first use of a file. Were mechanics, shop superintendents, and executives generally, to study their filing operations they would find that many files thrown away as useless could be used to good effect on some minor operation. The chilled edge of iron castings has spoiled many a good file, the name and manufacturer being roundly cursed, instead of the workman who used it in such a manner.

When executives see that every file used has a suitable handle, that work benches are at a proper height, that every worker is provided with a card and brush, and above all, that mechanics are educated to understand that a file is a fine cutting tool and requires care to produce its best work, then a great step forward in efficiency will have been made.

That Canadians may well look forward to the future with confidence is the view expressed in a public statement issued on December 21st by Sir Henry Drayton, Minister of Finance, in a review of the financial situation of the Dominion. Business conditions, he says, have slowly but surely improved during the past year. Notwithstanding a year of falling values and business difficulties, the finances of the country have wonderfully maintained themselves. The revenue, exclusive of railways, instead of falling, as of December 1st, has actually increased. Generally speaking the returns give reason to believe that Canadians can face the next year with a feeling of optimism.

MARKET DEVELOPMENTS

Mills Operating at Better Rate Than Expected

Steel Mills Did Not Close for Holiday and Production Has Been Held—Buyers Stocks Are Low and Business is Expected From That Quarter—Strip Steel Down in Price

A MORE optimistic spirit exists on the market. Pittsburg reports that the mills are operating at a better rate than was expected, in fact there is a probability they will be producing at a still higher rate about the middle of the month.

Buyers' stocks are low so that business is looked for in that quarter. While dealers are not expected to stock up to normal, the mills look for them to purchase up to 70 per cent. normal anyway.

The American Steel & Wire Co. has reduced its price on cold rolled strip steel from 3.75c to 3.50c. Continued price cutting by independents is responsible for this change.

Connellsville coke is softer all around, and the demand for foundry coke has been very poor since the middle of December, prices ranging from $3.75 to $4.50 according to brand. There is a movement existent for $4.00 and $4.25 coke, the theory being that foundrymen are jealous of what business they have and will not take chances on quality of product for the sake of saving a trifle on the coke used.

Montreal reports that the recent contract for Government Ice Breaker has been cancelled. No reason is given for this move. The various markets are very quiet in this district, although building operations are picking up.

Business is a little better in Toronto. Dealers are more optimistic regarding the future and feel that better times are coming. They realize, however, that to secure business they will have to go out after it. The small tool market expects a decided improvement shortly, when factories have completed their stock taking.

STEEL PRODUCTION BETTER THAN EXPECTED—STRIP STEEL REDUCED

PITTSBURGH, Jan. 9, 1922—The outstanding feature of the steel situation this week is that the mills are operating at a better rate, and have more business on books, than would be expected from the reports given out quite universally in December of there being a very dull market in steel products. Production and shipments, of course, constitute the crucial test of conditions in steel. Sometimes mills are disposed to paint the picture of their condition in colors that are somewhat too bright, but now it appears they have been selecting more sombre colors than were justified. Perhaps the explanation is the highly competitive market that has existed for months, the individual mill now being fearful lest its competitors think it has acquired more business than its share, and accordingly turn in and compete more strenuously still.

There has been very little closing of mills over the holidays, not enough to make any material difference in a month's production of the industry, and there is a distinct possibility that mills will be operated at a higher rate at the middle of this month than they were at the beginning of December. If this occurs it will be due to buyers having started to replenish stocks, which they reduced to the absolute minimum, far below normal, as the old year closed.

While the Carnegie Steel Company may not be a criterion of the industry as a whole, its case is important since besides being the largest subsidiary of the Steel Corporation, it is the biggest steel producing company in the country. In December the Carnegie Steel Company booked more business in actual shipping orders, than it filled, and December was the only month of 1921 in which it made such a showing.

Buyers' Stocks

At the beginning of 1921 many buyers had stocks of no small importance and some buyers added to stocks in January and February, not slowing down mill deliveries to them in keeping with the decrease in their actual consumption. Afterwards there were the most strenuous efforts to liquidate stocks. It was during this process of liquidation that steel production, at the middle of July, fell to a rate of no more than 20 per cent of capacity, represented by a rate of steel ingot production of barely over 10,000,000 tons a year. So low a rate could not possibly be representative of actual ultimate consumption, even if business generally was decidedly dull.

Probably the last of the excess stocks were liquidated by some time in October, that being the estimate of one very well posted observer. All buyers desired to have their inventory December 31, as low as possible, for a variety of reasons. There was the financial reason, and then there was the uncertainty in the minds of many buyers as to prices, and finally there was the natural desire, after the unusual times for two years previous, to get down to bottom and make a fresh start.

Tendency to Build Up

It is quite certain that stocks of practically all buyers are very low, and much below normal. There is a strong probability that there will be a tendency on the part of many, if not to a great majority of buyers, to build up stocks, not necessarily to normal or the average of previous years, but at any rate to an amount that will enable business to be conducted smoothly and efficiently, which is not the case when a large distributor or manufacturing consumer is constantly running to the mill with an order for a mixed carload to be rushed, and that is substantially what buyers have been doing for the past few months.

One can go farther than to say that this is a strong probability, for it is a fact that in some important cases the process of building up stocks has begun, in that orders were placed in December for shipment after January 1, for stocking-up purposes. One estimate is that buyers who adopt this policy will aim to restore their stocks to 70 per cent

of the quantity they have previously considered normal, or average.

Stocking up along this line probably represents the first improvement the steel industry can expect in demand, over and above the demand it has had in the past three months, represented by a mill operation at the rate of about 23,000,000 tons of ingots a year. Too much emphasis can hardly be laid upon the fact that this rate does not necessarily represent any increase in actual ultimate consumption over the early months of the year, even though it compares with a rate as low as about 10,000,000 tons at the middle of July and a production for 1921 as a whole of between 19,500,000 and 20,000,000 tons, for in 1921 there was a liquidation of large stocks.

It follows that something like 23,000,000 tons a year represents the minimum of steel demand, upon which there can be a building up or increase, as buyers replenish stocks and ultimate consumption increases by underlying financial and commercial conditions improving. A rate of 25,000,000 to 30,000,000 tons in steel ingot production may be attained before summer.

It is much better to look at mill operations from this tonnage standpoint than constantly to reduce the tonnage to a percentage of "capacity," for it is not proved that the capacity needs to be busy in order that the country be busy consuming steel. Many more people are engaged in consuming steel than in producing steel, and estimates of general activity should be based on the consumption of steel rather than on the percentage of productive capacity that is active. The productive capacity has doubled since 1910, but it does not follow that it requires twice as much steel to make consumers busy. The capacity is estimated now at 52,500,000 tons of ingots a year.

Reduction in Price

The American Steel and Wire Company has reduced its price on cold rolled strip steel from 3.75c to 3.50c, on account of continued cutting of the 3.75c price by independents. Otherwise nothing at all has occurred in the matter of steel prices in the past week. The market is really quite steady, both in that few changes are occurring in quotable prices from time to time, and in that the ordinary market prices are subject to much smaller concessions, for large and attractive orders, than was the case a few months ago.

To illustrate, the open or regular prices on bars, shapes and plates last August were several dollars a ton higher than regular prices now, yet a very large order could possibly be placed at as low a price then as now. The great increase in market steadiness is likely to encourage buyers to take hold in a broader way, instead of doling out orders for single carloads each at the last minute.

The market is quotable as follows: Bars, shapes and plates, 1.30c; hoops, bands and hot rolled strip, 2.00c; plain wire, 2.25c; wire nails, $2.50; standard steel pipe, 71 per cent basing discount; black sheets, 3.00c; galvanized sheets, 4.00c; tin plates, $4.75. Blue annealed sheets are not closely quotable. The lighter gauges seem to be on a base price of 2.25c while the heavier gauges appear to be chiefly a plate mill proposition.

Pig iron remains dull and quotable at $20 for Bessemer, $18.25 for basic and $19.50 to $20 for foundry, f.o.b. valley furnaces, freight to Pittsburgh being $1.96.

While $3.25 to $3.50 was done recently on furnace coke contracts for first quarter, $3.25 could be shaded at the present time, while spot can be picked up in small lots at down to $2.75. Demand for foundry coke has been particularly poor since the middle of December, prices generally ranging from $3.75 to $4.50, according to brand. A point about the market is that while usually the major part of the business is done at the lowest prices, just now there is more movement in $4.00 and $4.25 coke, the theory being that foundrymen are very jealous of what business they have and will not take chances on quality of product for the sake of saving a trifle on the coke used.

POINTS IN WEEK'S MARKETING NOTES

Locally, the steel business is in fairly good shape. Orders are not very frequent, but stocks are both low in quantity and price. This is an off season for the steel trade and lack of orders was expected. The chief point is that dealers are more able to cope with the situation than they were at the beginning of last year.

The metal market expects an improvement shortly, and small tool dealers are likewise looking forward to better business. The machine tool trade locally is not very brisk, but dealers are hopeful as to the near future.

Pittsburgh reports that the steel industry is in better shape than was expected. The mills have not closed over the holidays as was expected, therefore the production rate has kept up. In fact there is a possibility that the middle of the month will see a still higher production rate.

Dealer and buyers generally are expected to build up their present low stocks to about 70 per cent normal, according to Pittsburgh. This would mean a steady flow of business to the mills.

Cold rolled strip steel has dropped in price from 3.75c to 3.50c. Price cutting is responsible for the change.

The recent order for a Government Ice Breaker at Montreal has been cancelled. It is said that an Ice Breaker intended for the Russian Government has been substituted

Building operations in Montreal district are improving. Conditions in Nova Scotia are quiet, the Dominion Coal Co. operating only two days a week. All other lines in Montreal market are very quiet.

ALL MARKETS ARE IN BETTER SHAPE

TORONTO, Jan. 9, 1922. Although very little business is being closed on the local market, conditions generally are much better than they were a year ago. For example, take the iron and steel situation. At this time last year, dealers found themselves with a very heavy stock of high priced material, or rather, steel which was purchased at high prices, but could not be marketed at anything near the purchase figure. During inventory dealers had to incur very heavy losses, with the result that the market was in poor shape.

Sheets bought at current prices, dropped overnight; other lines made similar spectacular dips, leaving the buyer in a quandary as to the proper time to place his order. To play safe, he withheld his business up to the last possible moment, the dealer being the loser. So much for 1921.

Today we find dealers taking inventory once more, but in this case stocks are low, both in quantity and price. Not that the supply on hand is inadequate, but simply that dealers have followed out a careful policy throughout the year.

As one merchant put it: "We have incurred several losses during 1921, but they have all been marked off. What happened last year is a closed book, so far as we are concerned. Our stocks are just of the correct proportions. It is material purchased at a reasonable figure, so tha we have brought our prices down to present levels, without difficulty."

Improvement Expected

Everyone in the steel business is convinced that the present year will be an improvement over the last, but that this upward tendency will only come through hard work. "We've got to dig deep to get the business," is the way one dealer put it. Steel men realize that the small town business, namely "Farmer" trade, will be poor this year. The farmer has had a tough time of it during the past season, and he is not going to spend any more money than he can help.

Another large user of steels, the agricultural implement manufacturer, is feeling the present depression, with the result that dealers are practically eliminating them from their list of possible buyers. In fact we were told on good authority, that a certain implement fac-

tory had actually more bars to SELL than a local steel dealer has in stock. As long as this condition exists, merchants cannot look for business from that quarter.

In spite of the above, the steel market, taken as a whole, is in much better shape than the spring of 1921, and as mentioned before, dealers are convinced 1922 will see an improvement, but only a gradual one.

The Metal Market

Metal merchants are up to their eyes in stock taking. This market is also in a much healthier condition than it was last year, and dealers feel that better times are ahead. They do not expect them to improve at once, but look for a gradual upward trend. There are no changes in price, the market remaining firm in all lines. Another two or three weeks should see a strengthening tendency in various lines, according to some dealers in this business.

Machine Tools

It is almost too soon after the new year to expect much improvement in the machine tool market. Several interesting enquiries are being received which look like good business in the near future. One dealer has secured additional space for the placing of new machines in stock and, as he says, "this step should show conclusively that I believe the Canadian machine tool market has a prosperous future. We will have to go out after business," remarked this dealer, "and I feel sure we will find it eventually." There is a better feeling on this market which is worth noting.

Small Tools

Dealers in the small tool lines are simply marking time. They feel that until manufacturers are through inventory there is not much chance for them. Once the stock on hand is compiled, the various plants will be sending out their requirements, and the small tool market will pick up accordingly.

IMPORTANT CONTRACT CANCELLED BUSINESS IN ALL LINES VERY QUIET

MONTREAL, Jan. 9.—The first week of the New Year has been one of the quietest of many years, in the metal working industries. The production of steel is at a low point and the price continues to be correspondingly weak. Owing to the general dullness of the times many firms have closed down for short periods, and do not exhibit any great desire to re-open their premises. Business in merchant bars and structural steel shapes has fallen to a very small volume. For the last few weeks the amount of trade in sheets and plates has dropped off a great deal. Other lines of steel are quiet, more so than usual, as business has not been resumed in a normal way since the interruptions of the holiday season.

The recent ice-breaker contract placed with Canadian Vickers' has been cancelled. No definite reason is given, but the fact remains that this much desired order has for the time being, at least, vanished into thin air.

Industrial Conditions

Building operations in the city of Outremont amounted to $1,297,115 for the year 1921, which figures have only once before been exceeded, and that was in 1913. Building prospects for this city in the coming year are very good. Over $400,000 worth of building is already contemplated for the early spring.

Industrial conditions in the Eastern Townships appear to be in good shape, and the city of Sherbrooke reports a very satisfactory year.

The large engineering industries in and around Montreal have not had a very successful year, as was to be expected. These concerns, have in most cases made net profits, but in order to fully meet the demands of dividends on their stocks and bonds, have been compelled to draw upon the large reserves built up in the last few years.

Conditions in Nova Scotia continue to be very quiet. The Dominion Coal Company are operating only two days a week pending a settlement of the wage disputes.

The pig iron producers have experienced one of the quietest weeks in their history. There are no new developments in prices while the demand has fallen off to practically nothing.

Machine Tools

In the machine tool field, business is equally as quiet. It was a foregone conclusion that there would be little moving in machine tools before spring, so present conditions were not unexpected.

The small tool and supply business has suffered badly during the last few weeks, but there is every prospect that it will soon improve when machine shops are re-opened.

Metal Market

Non-ferrous metals are very quiet. Practically no business is offering, and no changes in price have been noted with the exception of aluminum, which is gradually coming down, following the lead set by the other metals some time ago.

The scrap metal market remains as before, no activity in any line being evident.

Did you ever do repairing and lose money on it? Read in the January 19th issue of Canadian Machinery how it can be done at a profit. The special article will be "Repair Jobs that made us a Good Profit."

AUTOMOBILE INDUSTRY IN GREAT BRITAIN

"The automobile industry of the United Kingdom is passing through the most trying period in its history." This is how Trade Commissioner J. E. Ray at Manchester, England, sums up the automobile situation. Inquiries instituted among the manufacturers in Manchester and district reveal very discouraging conditions unrelieved by any promise of better times in the immediate future. The high costs of production and the general slump in trade are responsible for the dearth of orders. Further, optimism during the trade boom of 1919-20 swelled the sources of supply, so that the manufacture of automobiles and transport vehicles was overdone. In 1919, trade journals and newspapers, inspired probably by the example of producers in the United States, were insistent upon mass production as an indispensable lever for raising Great Britain to a more secure footing in the markets of the world.

Business men caught the malady, continues Mr. Ray, especially the automobile manufacturers who undertook bold extensions of plant, and it is only just beginning to dawn upon them that industrial methods, though successful in one country, are not of necessity bound to be successful in every other country. Defenders of the mass production system may seek refuge in the unforeseen trade depression, but it has to be admitted that several British concerns, which set out to reduce costs of production by the mass system, have found their unit expenditure to be higher than that of firms producing on a similar scale but on the unit system.

Statistics show that the imports of touring cars to the end of September 1920 were 4,276; of commercial vehicles 2,112, and of chassis 3,019, more than half of which came from the United States, with Canada, France and Italy next in order. These imports were nearly 30,000 less than in the corresponding period of 1920, and nearly 2,000 less than in a similar period in 1913.

The exports of automobiles for the first nine months of 1921 were 1,557, of commercial vehicles 591, of chassis 847, and of motor cycles and tricars 7,039, which were less than half of the numbers exported during the corresponding nine months of 1920, and considerably lower than the exports of the corresponding period of 1913.

Doubtless the industry is terribly strained at the present time. A good deal of price-cutting is taking place with a view to stimulating demand. Quite a number of manufacturing concerns, some of them owning huge plants, have gone into liquidation, concludes Mr. Ray, and it is believed that, apart from trade depression, a good number of producers must ultimately be squeezed out by excessive competition.

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

Experiments in Ceylon have proved that tractors are very useful on coconut plantations.

Moving pictures, accompanied by lectures are being used extensively in China to show the progress of industries both there and in other countries.

It's the litt'e things that count. Just what this means to the trade will be understood after you read "Repair jobs that made us a good profit," in the January 19th issue.

It is reported that a cement works with £500,000 capital will be started at Brogan's Creek in the Rhylstone district of New South Wales.

The Pronovost Universal Wheel Co., Montreal, Que., has been incorporated to manufacture automobiles, etc., with $50,000 capital stock.

The Collins Power Co., Windsor, Ont., has been incorporated to manufacture automobiles, machines, engines, etc., with $1,000,000 capital stock.

Brazi ian farmers are increasing their use of up-to-date agricultural machinery, and a return to better conditions will bring a renewed demand for such articles.

A firm of engineering specialists in refrigerator plant and pumping machinery in the Orange Free State request particulars from Canada in the above line, including compressors.

The Black & Decker Manufacturing Co., Baltimore, Md., announce that effective January 3, 1922, they will make a freight allowance on shipments of 100 lbs. or over to points in the United States and Canada.

A Chinese automobile, said to be equal in quality and workmanship to the foreign make, has been turned out by the Yantze Machinery Works. The intention is to compete for the China market.

The Canadian Department of Trade and Commerce is inviting tenders, which will be received up to January 31st, 1922, for a weekly or fortnightly steamship service from Halifax or St. John to the West Indies and British Guiana.

The Newfoundland Government has decided to pay a bounty of $30 per ton on all schooners over 25 tons, and up to and including 50 tons register built on the island this winter and fully equipped and ready for sea about July 1st, 1922. The object is to assist the merchant marine to replace the numerous vessels lost last year and to provide employment for those out of work.

The city of Winnipeg, Man., have recently purchased 3,000 meters from the Canadian Westinghouse Co., the Packard Electric Co. and the Samgamo Co.

Electrical contracts have been awarded for the High School to be erected at North Toronto at an estimated cost of $160,000.

The Canadian Electrical Supply Co. are now handling the "Brantford Locomotive" electric washer manufactured by the Brantford Washing Machine Co. The territory includes Eastern Ontario and the Province of Quebec.

Steel motor coaches, having accommodation for 60 to 80 passengers and a speed of 45 miles, are being placed on the Canton-Kowloon railway line by the Chinese Government. Several cars have been purchased in San Francisco.

The following are new trade inquiries for Canadian products: A firm of Canadian agents at Bridgetown, Barbados, would like to obtain a Canadian connection for a supply of wire nails, rivets, bolts, nuts, etc.

Electrical contracts have been awarded on the 10-room school being erected at Melrose and Verdun Avenues, Verdun, Que., at an estimated cost of $100,000.

The Gaspereau Light and Power Co. have recently placed contracts for the installation of a new power unit to be installed in their White Rocks, Nova Scotia, plant. This new unit will add about 50 per cent. to the present production.

The Ontario Gazette announces the incorporation of the Matachewan Co. with a capitalization of $1,000,000. Head office, Toronto, Ont. It is understood that they will develop water power from the Montreal River, in the Matachewan area, Northern Ontario.

About 41 men were taken on the Collingwood Shipbuilding Co.'s drydock on January 3rd at Kingston, Ont., and were set to work on the steamer Keybell. It is expected that more men will be taken on during the week.

London, Ont., is making an addition to the London Technical and Art School to be erected by the Board of Education at an estimated cost of $100,000. The program for the year provides for the erection of new buildings to cost about $400,000, including a new 14-room school in West London and the first unit of what will be a 17-room school in the Ealing district of East London.

The city council of Sydney, N.S., plan alterations and improvements to water works to cost $150,000.

At Dauphin, Man., a by-law has been passed authorizing expenditure of $160,000 for the erection of a hospital.

The Beeby Range Co., Brockville, Ont., has been incorporated to manufacture stoves, furnaces, etc., with $500,000 capital stock.

General contract at $299,135 for erection of a school costing $425,000 on Main Street at Hamilton, Ont., has been awarded.

The erection of a hotel at Quebec City, Quebec, at the cost of $300,000, is contemplated by Mr. N. L. Dhan, Palace Hill.

In the city of New Westminster, B.C., the city engineer, Stewardson, is preparing plans for reconstruction of water works to cost $250,000.

Plumbing and heating contracts for memorial hospital costing $110,000 for the hospital board of Orillia, Ont., have been granted.

Building figures for the city of Windsor, Ont., for 1921 show an increase of $272,820 over those for 1920. Buildings valued at $5,123,130 were erected there last year. A million-dollar hotel is included in the total.

Tenders have recently been received for the erection of a 44-room school at Hamilton, Ont., and it is expected that P. H. Secord & Sons will receive the contract. The total cost of this school will be $400,000.

Mr. A. Mason, Acton, Ont., has purchased an old electric power plant and will remodel and equip the plant as a woollen mill. He plans to build an additional storey next year, at an estimated cost of $36,000.

A Johannesburg firm of agency engineers make inquiry re obtaining in Canada an agency in all lines needed for engineering supplies, except belting and pulleys. One of the largest engineering firms in Johannesburg are requesting quotations for bare copper wire, copper press bar and rods.

Arc welding for repair and reclamation, general applications of arc welding, and arc welding for manufacturing processes are described and illustrated in Leaflet 1825, just published by the Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa. A story is told of how costs are reduced by the use of arc welding.

The value of permits issued for December by the city architect's department of the city of Toronto was $2,100,606 as compared with $1,117,083 in December of 1920. This total shows an improvement on the November figures.

ROTARY DIE-HEAD

Various large consignments of German goods have been arriving in Argentina, according to a report from England. These goods included agricultural machinery, boiler tubes, barbed and fencing wire, constructional iron, paint, pianos, rails, refrigerators, sewing machines, and steel tubes.

Britannia Beach, B.C., lists have been received on structural steel necessary for the rebuilding of the concentrator plant. The estimated cost of the steel equipment for the new building is between $150,000 and $175,000. The completed concentrator will cost approximately $500,000.

A $3,000,000 highway through the island of Montreal, to extend from the Bridge terminal at the extreme east of the island to St. Anne de Bellevue, will soon be started on. Work is expected to begin during the coming year. It is to be built in sections and will be 150 feet wide altogether.

Vancouver is advancing among the Pacific coast ports and is becoming one of the world's distributing centres, particularly for cargoes from the Orient. This is borne out by the customs department figures for that port for 1921. Customs receipts for the year ending December 31 amounted to $12,662,772 compared with $10,442,332 for 1920 and $8,547,689 for 1919. Shipments of British Columbia lumber for 1921 by water from mainland ports in the Province of British Columbia to foreign countries reached a grand total of 164,000,000 feet.

An exhibition will be held in Singapore on the occasion of the visit of the Prince of Wales. It will open from March 31st, to April 8th, 1922, and will be under the auspices of the Governments of British Malaya, Borneo and Sarawak. Further information may be obtained from the Malay States Agency, 88 Cannon Street, London, E.C. 4.

Industrial conditions in Brantford have shown some vast improvements. The Massey-Harris Co. now has 600 employees, a gain of 200 in the last two weeks. They are working 3 days a week, 8 hours a day. The Cockshutt Plow Co. has 350 men 3 days a week 8 hours, with foundrymen working 9 hours. The Waterous Engine Works is going 5 days a week 9 hours a day with 150 men employed. The foundrymen are working 3 days a week but it is expected that they, too, will take on the full week.

After extensive and thorough experimentation, blotting paper of the finest quality is now being produced in Canada. Hitherto all blotting paper used in Canada has been imported, the imports being valued at about $500,000 per year.

Niagara Falls, Ont. The month of December shows a successful building year; 263 permits were issued valued at $1,145,589. Comparing this item with $473,065, which was the total last year, it shows a considerable increase.

The Rt. Hon. Stanley Baldwin, M.P., President of the Board of Trade, speaking at Liverpool, England, recently, said: "I am advised that in India the bottom has been reached, and that they have had an excellent monsoon, which generally means the purchasing power of that country is improved for the ensuing season. I am told that there are signs of improvement in Japan, the first country to feel the slump. Our advice from the Dominions and South America is that feeling is a good deal more hopeful."

Other reports from Sydney, Australia, state the recent improvement in business is sufficiently marked to warrant importers indenting on an increased scale and indicate that the greatest slackness has most probably passed. A steady demand is being experienced by wholesale merchants in New Zealand, who also report a shortage in a large number of individual imported lines. Reports recently received from all parts of Chile confirm the opinion held by prominent business men in Santiago that the commercial outlook in Chile is brighter than it has been for many months.

The total amount of contracts awarded for construction in Canada in 1921 are given in the Canadian Building Review. This figure was $240,133,300 for the year 1921 against $255,605,500 in 1920, $190,028,300 in 1919 and $99,842,100 in 1918. Of these totals the amount of business buildings erected was practically unchanged and constituted the largest, at $84,721,700 against $86,075,200 in 1920. Returns for December, 1921, show $19,118,500, being the second largest December total on record, being exceeded only once, and that in the boom time of December, 1912.

The British Agent at Moscow reports that as the result of a special agreement with the Commissariat for Foreign Trade of the Russian Soviet Government, a company known as the Russian Export and Import Company, has recently been formed in Moscow to do business with foreign countries on behalf of the Soviet Government, on a commission basis. The founders of the company, according to the Empire Mail, were formerly leading merchants in Moscow, and were in close business relations with important British and foreign firms. The formation of this company, which is the first step towards removing the foreign trade of Russia from the direct management of the Commissariat for Foreign Trade, is for the purpose of exporting Russian produce abroad and importing foreign goods in Russia. The goods offered to the company for disposal abroad include flax, goat skins, horsehair, bristles, caviare and scrap iron.

Fire losses in Canada during the week ending December 21st are estimated by the Monetary Times at $798,400, compared with $457,500 the previous week.

The Chile Copper Co.'s plant calls for an increase in capacity from 15,000 tons to 35,000 tons a day as soon as conditions warrant. This should give the company a capacity for producing 300,000,000 pounds of copper annually and on the basis of 1920 cost of producing more than one-third of this amount, it is estimated that Chile should then send out its copper for 8c per pound, if not lower.

The total value of permits issued by the building department at Montreal for the year just ended passed the $21,000,000 mark, an increase of approximately $7,000,000 over the 1920 figures. Montreal's record building year was 1913, when construction to the value of approximately $27,000,000 was carried out. However, last year's increase was very satisfactory and prospects are even brighter for 1922.

Another large hotel is rumored at Quebec City, P.Q. Mr. C. J. Lockwell, representing the Canada Hotels Co., it is reported, briefly waited on certain city officials and submitted a scheme for the erection of a ten-story hotel to cost between $1,500,000 and $2,000,000 on Montcalm market. This company, Mr. Lockwell stated, intend erecting a string of eight hotels in large Canadian cities, including the following: Quebec, Montreal, Toronto, Three Rivers, London and Kingston.

The production of chromite during 1920 in the Province of Quebec, amounted to 10,585 tons, valued at $247,730. This is a slight increase compared with the previous year, when the figures were 8,184 tons valued at $223,331. The greater part of the chromite produced is in the form of concentrates running 50 per cent. and over of chrome sosquioxide, although a small quantity is also shipped in lumps, locally called crude ore, which is ore sufficiently rich to be shipped without requiring concentration.

In 1919 there was published by the Engineering Station of the University of Illinois a bulletin, No. 111, dealing with the forms in which sulphur occurs in coal. The research work in connection therewith was conducted in the Chemical Laboratory of the University of Illinois by S. W. Parr and A. R. Powell, who developed successful methods for determining quantitatively the different chemical forms of sulphur in coal. Bulletin No. 125, by H. F. Yancey and Thomas Fraser, just issued by the Engineering Experiment Station, deals with the manner of occurrence and the distribution of the various forms of sulphur in the coal bed. The experimental work was undertaken as a part of the

United States Bureau of Mines plan of research on coal preparation, and the application of the information secured to the problem of producing cleaner coal was the principal objective. The solution of this problem must of necessity rest to a considerable extent upon an intelligent knowledge and appreciation of the physical and the chemical forms in which sulphur occurs in a particular coal, and how it is distributed through the coal in the bed. Copies may be had without charge by addressing the Engineering Experiment Station, Urbana, Ill.

Two British shipping companies have been successful in getting important contracts in America, although competition was said to be unusually keen. The Cunard Company has been awarded by the Standard Oil Co., of New Jersey, the contract for the transportation of case oil to Levantine ports in 1922; and the Furness Withy Company (Prince Line) has been given a contract by the Baldwin Locomotive Co. for carrying 85 locomotives from Philadelphia to Buenos Aires.

The knitting goods trade is looking towards the New Year with confidence. In spite of the disturbances in commercial affairs during the past twelve months, a satisfactory volume of business was done. The year of deflation has been passed and toward the end of the year there was very satisfactory activity in most of the Canadian mills. A number of the mills enjoying good connections with the wholesale and retail trade were unable to handle all the business that was offering in goods for autumn delivery. Some were working on double shift, endeavoring to meet hosiery requirements, and even then had to turn away some business.

New Machine Shop at Dresden, Ont. Herbert Lamb, formerly with Vickers & Maxim, Barrow-in-Furness, Eng., but for the past eight years head road man for The Canadian Fairbanks-Morse Co., Toronto, and W. D. Lawrence of Dresden, have opened a machine shop at Dresden, under the firm name of Lawrence and Lamb. They will specialize on the installation of water-works systems, fire-fighting pumps and apparatus, also individual lighting systems. They have been operating since December 1st and have already booked several good contracts. They are well pleased with the prospects for the coming season.

Before the engineering section of the A.A.A.S. now in convention at the University of Toronto, Mr. John Hartman, consulting mining engineer of Montreal, pointed out that in the most active periods some 38 per cent. of the total tonnage covered by the Canadian National Railway system come from the products of Canadian mines. Mr. Hartman outlined the progress of mining in Canada during the past fifty years, dealing emphatically with the remarkable increase in output of silver in the last decade. In this connection he noted that in the last twenty years Canada's silver production increased from $3,000,000 to $13,500,000 annually, while the annual gold production has shown a decrease in the twenty-year period. In the same period the production of coal had grown from 6,500,000 tons to 16,000,000 short tons.

Speaking on conditions in the United States, the National Bank of Commerce, New York, says that everything seems to indicate that the year 1922 as a whole will be more satisfactory to business than the year just ended. Their forecast is that profits will depend more on economy of operation than on expansion of volume. With the many favorable factors now operating, they continue, business men should not fear to make plans for the new year, but they should plan with care and conservatism, and with constant effort toward reduction of costs.

Financial improvement continues. Progress has been made in reduction of excess stocks of manufactured goods. Accumulations of raw materials have been reduced. The rate of production in the major industries has shown little change during the closing weeks of the year. Losses in some lines have been offset by gains in others, the net result being that the gains over the low level of the earlier months of 1921 have been held.

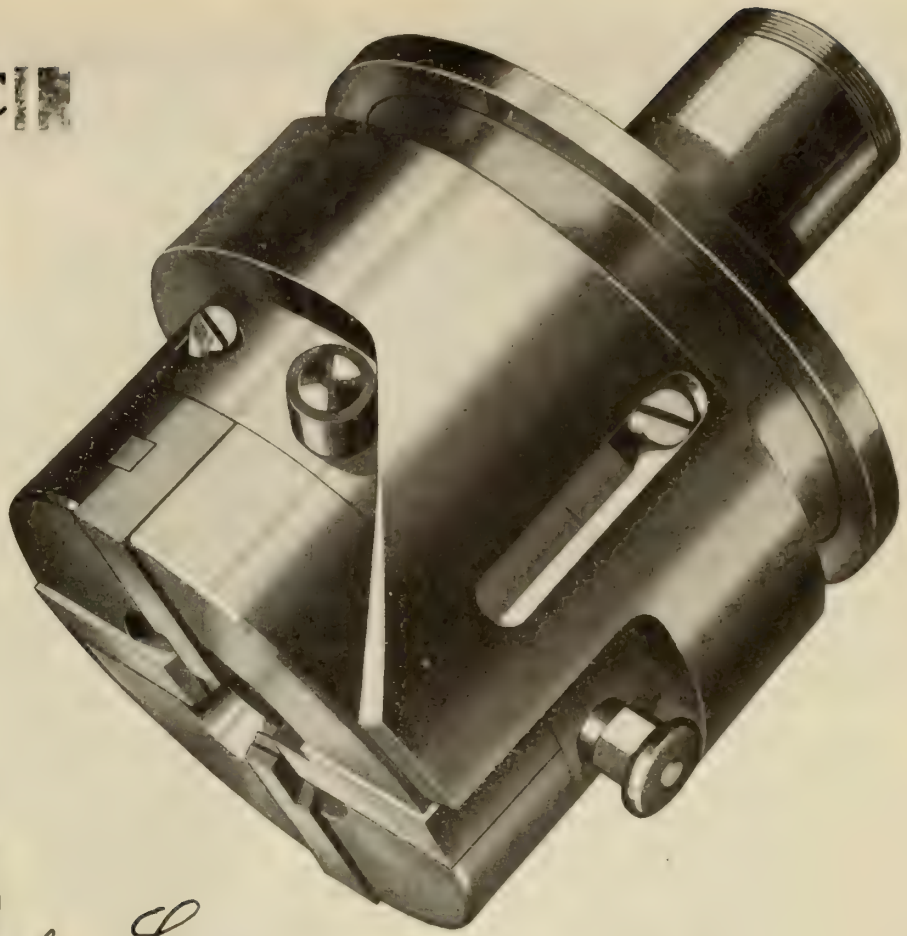
Dresden, Ont. The water commission have completed their new pumping system which consists of two double suction pumps direct connected to two 25 h.p. three phase, 25 cycle, 550 volt motors. The equipment also includes a centrifugal pump, direct connected to a gasoline engine. The pumps are attached to a tank 135 feet high which keeps pressure on the mains even though the pumps are stopped. The former installation of two steam pumps and two boilers is still intact but will be discontinued as it is considered that the gasoline can be depended upon in case of a possible shortage of electricity.

It is the intention during the coming summer to change the water supply, which is simply that of the Sydenham River to wells similar to those sunk in connection with the water system, London, Ontario, thereby insuring an abundance of the purest of water for domestic purposes. Mr. Herbert Lamb was the engineer in charge of the installation of the present system.

An entertainment will be given on January 14th, 1922, at the Massey Hall, Toronto, under the auspices of the Ontario Safety League which should prove of special interest to those who are directly or indirectly concerned in accident prevention. The programme will principally consist of a play on shop life, entitled "Fixing the Responsibility for an Accident." This was staged by members of the National Safety Council at their Milwaukee Convention a couple of years ago and repeated in Hamilton under the auspices of the Public Safety Committee of the Hamilton Chamber of Commerce before an audience of about 3,000, with such success that the committee in charge have been asked by the Ontario Safety League to repeat it at Massey Hall. Moving pictures will also be shown which depict the dangers and hazards of the streets in the business section of large cities where automobile traffic is heavy. Every conceiv-

RACTS

ES



Massachusetts Ave., Washington, D. C., is prepared to supply to those interested, free information about scientific instruments, apparatus and supplies, laboratory construction and equipment. The following are samples of requests answered recently: "Where may we purchase inexpensive photomicrographic apparatus?" "Where may a human skull be purchased?" "Who manufactures a good grade of selenium cells?" "Advise where lantern slides on European Geography may be obtained." "Where may the Lummer-Brodhun cube be obtained?" "What concern makes gauges recording in fractions of an ounce?" "Where may apparatus and accessories for the study of sensitiveness of photographic plates be secured?"

The Natural Resources Intelligence Branch of the Department of the Interior has published a map showing the leading natural resources of each province. In Nova Scotia mixed farming, mining and fishing predominate; in Prince Edward Island fur-farming and agriculture. New Brunswick has large areas of timber, while mixed farming and fruit growing are outstanding interests. In Quebec may be found a wealth of timber for pulpwood, al minerals such as asbestos, graphite and molybdenite, while in Ontario somewhat similar opportunities exist. In the Prairie Provinces the prospective settler may obtain adequate returns on capital and labor in either grain growing, mixed farming or ranching, while in British Columbia timbering, fishing, fruit-growing and mining are among the leading industries. In addition to information on natural resources, the map shows all railways and trade routes. An interesting and valuable feature is a series of comparative diagrams illustrating the production and exports of the various provinces. A copy of the map may be obtained free of charge upon application to the above mentioned department at Ottawa.

Industrial Works, Bay City, Michigan, is distributing free upon request Catalog No. 113, illustrating and describing the Type BC "Industrial" Crawling Tractor Crane of 20,000 pounds capacity.

This crane is pre-eminently adapted to the needs of road contractors, lumber and coal dealers, gravel, sand and stone producers, foundries, railroad reclamation and storage yards, and moderate-size manufacturing plants.

GEOMETRIC ROTARY DIE-HEAD

Right on the Lead

One of the Die Heads that has put production on the increase and costs on the decrease.

This Rotary Die Head, which made itself famous on the Geometric Threading Machines, is adaptable for rotating on other types of machines, such as Drill Presses, Bolt Cutters, etc.

Let us know the machine on which you desire to use the Geometric Rotary Die Head, and a suitable shank will be applied.

To Get Quick Production of Screw Threads Without Waste, Try a Geometric. They are sent on trial to Reliable Concerns.

THE GEOMETRIC TOOL COMPANY

NEW HAVEN CONNECTICUT

Williams & Wilson, Ltd., Montreal.

Canadian Agents:
The A. R. Williams Machinery Co., Ltd. Toronto, St. John, N. B., Halifax, N.S. Vancouver, B. C.

BASIC BUSINESS CONDITIONS ARE MUCH IMPROVED—COSTS ARE DOWN

THE business world enters the New Year with hope and optimism. The trials and difficulties of the adjustment year have not been in vain. Business is fundamentally in a much sounder condition than it was twelve or six months ago. This should be manifest in a gradual revival of activity from now on, in the re-opening of factories, and in the lessening of the volume of unemployment.

The year just closed, says "Financial Post," witnessed the working out of a broad process of price deflation and liquidation. Commodity prices now represent a sharp discount from the rates prevailing a year ago, and the average wage level is likewise substantially reduced. Goods offered to the public in the coming months will have been manufactured at the lower costs of production, and one of the chief deterrents of trade throughout the past year—the relatively high costs of manufactured goods—will have been largely eliminated.

Stocks Have Been Reduced

Retail stocks have been very drastically reduced during the past twelve months, and on the whole now are incapable of supplying public demand for longer than a comparatively short period. The Christmas trade was an encouraging feature of the season's business. Turnover on the whole was above that of the previous year, although actual revenue will show a small decline. The public bought freely, however, and the demand did much to bring merchants' stocks to a state of near depletion. Such a situation must lead to replacement on a larger scale to keep pace with the public demand, and this will in turn mean larger business for the wholesaler and manufacturer.

Sentiment at the new year is particularly hopeful, and is based upon specific instances of larger business pending. To quote one case, the clothing industry will benefit to a very considerable degree by the large orders that will be placed for uniforms for certain classes of municipal employees. For example it is understood that the Dominion Government will shortly place a contract for 5,000 Boy Scout officers' suits; the postal department will contract for some 10,000 postal employees' uniforms in January. It is reported that the Toronto Transportation Commision will shortly order 2,500 blue and grey uniforms for the street car employees, to be priced around $37 per suit; the Hamilton Street Railway will likewise let contract for 1,200 uniforms, and the Winnipeg Electric Railway, 1,400. Throughout the country there will be a fairly extensive ordering of uniforms for police and fire departments, bringing the aggregate of this class of work to a fairly substantial total, and spread around among the different clothing manufacturing concerns will enable these firms to get their organizations together in readiness for the larger business ahead.

Necessity for Replacement

The most important factor entering into the business situation at the present time is the necessity for replacement of all classes of goods. The public has been buying conservatively, likewise the retailer and wholesaler. The manufacturer too has radically curtailed his output.

Goods have been gradually reduced without a production to keep pace with the rate of depletion, and the result is that the world's supply of goods and commodities is now very substantially below nomal. To the aggressive business man this situation lays open the door of opportunity. If he can produce the goods at a price and of a quality to meet the public appeal the goods can be sold, but if prices are to be still maintained at inflated levels, then the depression in trade, and in his industry especially must continue. A period of the keenest type of competition lies before, and the dealer and manufacturer who is the first to thoroughly eliminate inflation from his prices through lower production costs and production efficiences will be placed in a position of inestimable advantage in the contest for business.

Cost Adjustment

Fortunately much progress has already been made in this direction. The breakdown in prices of raw materials, the decline in the cost of living, and reduction in wages, have reduced the cost of manufacture in all staple industries. Aided by the recent substantial adjustment of the exchange markets toward par there is the further possibility of competing successfully in the world's markets, and very little is needed to set the machinery of industry and commerce going.

International trade has been at a standstill, through the unsettlement of international exchanges, and thus conditions have but served to intensify worldwide and local depression. There has been a gradual improvement of Canada's trade balance of late, due in part to the decline in the importation of raw materials, but with exchange gradually strengthening there is a basis for the belief that the improvement may be of a permanent character.

Recent advances in the price of government bonds is one of the phases in the cycle of adjustment and denotes an increasing easiness of money. When industrial conditions are righted this money which is now going into securities will be turned into productive channels.

If a fire starts from kerosene, do not throw water on it as water will spread the flames. Sand or flour is the best extinguisher, or it may be smothered with a woollen rug, table cloth or carpet.

CATALOGUES

Safety Switches and Panel Boards is the subject of catalogue 12-A, dated 1921-1922, which is now being distributed by the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa. This catalogue is profusely illustrated with views of installations of safety switches in the shop, in the office, and in the home. Dimensions and list prices of these switches are given in detail. Some of the subjects that are discussed are the railway type safety panel boards, the safety car lighting panels, the auto-lock control panels, the dead-front and dead-rear safety switchboards, the live-front knife switches and many other devices.

We have received from the Sterling Engine Co., Buffalo, their catalogue illustrating gas and gasoline engines for driving centrifugal pumps, for use in water works, industrial plants, and fire protection systems. Several of these units have been installed in Canadian cities. The catalogue is well illustrated and all the necessary information is included. Diagrams showing the space occupied by different sized installations are also given.

The Canadian Ingersoll Rand Co., Montreal, have issued in the form of a bulletin the paper on "Steam Condensing Plants," read before the Baltimore section A. S. M. E. in May last. The paper is a very interesting one, and contains much valuable information for those interested in the operation of this type of apparatus. Bulletins 1028, 1094, 9032, and 9224 covering low level and surface and Barometric condensers are now available and will be supplied to readers of Power House on request by the Canadian Ingersoll Rand Co.

Westinghouse Turbine Generator Units are described and illustrated in Circular 1094-B, just issued by the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa. This publication contains a discussion of the reactance and impulse types of turbines, both the semi-double flow type and the multiple cylinder type. Bleeder turbines and geared turbines are described, and each part of the turbine is elaborately treated. The generator is also discussed in detail, and illustrations are given to show the latest types of construction.

The Combustion Engineering Corporation, New York, announce the opening of a new branch office at 806 First National Bank Building, Pittsburgh, Penn. This office will be in charge of Mr. C. W. Stripe, formerly manager of the Philadelphia office.

Hoar frost presents beautiful crystalline forms because the atoms of water, when deprived of the degree of heat necessary to keep them in a fluid condition, arrange themselves in groups, giving rise to what are called crystals.

Classified Opportunities

PATTERNS

TORONTO PATTERN WORKS, 65 JARVIS Street, Toronto. Patterns in wood and metal for all kinds of machinery. (ctfm)

BRANTFORD PATTERN WORKS ARE PREpared to make up patterns of any kind—including marine works—to sketches, blue prints or sample castings. Prompt, efficient service. Bell 'Phone 631; Machine 'Phone 733. Brantford Pattern Works, 49 George St., Brantford, Ont. (ctfm)

FOR SALE

FOR SALE — FORTY HORSE-POWER VERtical Boiler 120-lb., steam, Ontario inspection, 129-2" tubes 5' 9" long, 74 of them new. Complete with grates, smoke stack and cast iron base. $500.00 F.O.B. Port Arthur.

Return Tubular Boiler 72" x 18' for 115-lb. steam, Ontario inspection, 84-3½" tubes, straight seams, triple rivetted butt joint. This boiler with full flush front and doors, arch-plates, soot doors but no grates or fittings, for $900.00 F.O.B. Port Arthur. Port Arthur Boiler Works. (c2m)

FACTORIES FOR SALE — TWO DESIRABLE plants; one at Mount Forest, constructed of brick, floorage over 40,000 square feet, formerly operated by Weir Wardrobe Co.; and the other at Guelph, stone florage over 50,000 square feet, formerly operated by Dominion Casket Co. Apply Box 777G, Canadian Machinery.

SPACE FOR RENTAL

FLOOR SPACE — SEPARATE ENTRANCE— Suitable for machine shop or light manufacturing, with power, reasonable rental with long lease if desired; also small foundry building, suitable for 4 to 6 moulders; in good manufacturing town; railway centre. Apply Box 789T, Canadian Machinery.

Modern Marine Machinery

Automatic Steam Towing Machines, Ship Windlasses, Cargo and Deck Winches, Steam Capstans, Dock Gypsies, Steering Engines, Hydraulic Freight Hoists, etc. Grey Iron and Brass Castings. Special machinery built to order. The Corbet Foundry & Machine Co., Limited, Owen Sound, Ont. (52)

BUSINESS CHANCES

WANTED—BY AN ESTABLISHED CONCERN. Twelve to fifteen thousand dollars for a period of from one to three years, to take care of business expansion. This concern will stand the fullest investigation. 8% is offered with ample security to principals only, with an opportunity of becoming permanent associates with the partners, if mutually satisfied. Box 767, Canadian Machinery. (etfm)

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

Men the Boss Holds On To

Can the Boss depend on you to handle any job he gives you—and turn it out right?

If he can, you're the kind of machinist he'll want to hold on to.

A good outfit of Starrett Tools, plus a thorough study of how to use them, will go a long way toward helping you to become that sort of machinist.

As to how to use tools—if you haven't already got them, buy a copy of the Starrett Book for Machinists' Apprentices, or the Starrett Data Book for Machinists. Price 75c each. Your dealer can supply you, or we will send copies postpaid on receipt of price.

Send for Catalog No. 22 "3."

Announcing Another Step in the Path of Progress

OSBORN'S
RUSTLESS PLASTIC STEEL
(RUSTLESS IRON)

for articles and parts of machinery which do not require a cutting edge or particular hardness but are subject to corrosion; and which must be kept bright and free from rust.

PROPERTIES:

Neither rusts nor tarnishes.

Non-rusting characteristics are the same as ordinary Rustless Steel, but it is very plastic, hence the name.

Is much softer than ordinary Rustless Steel, and requires no special treatment to bring out its rustless properties, but tensile test results varying from 68,000 to 180,000 lbs. per square inch can be obtained by special treatment.

Can be stamped, punched, pressed, chased or engraved in the cold condition and none of the difficulties experienced in the drop stamping of ordinary Rustless Steel are encountered.

Can be bent cold in its polished state to a diameter equalling its own thickness without showing signs of fracture.

Can be put in a **silver bright condition before being worked,** and, if cold worked it is only necessary to highly polish the article after it has been made, thus saving the hardening which is a trouble and which causes distortion.

Is stronger than brass or nickel and therefore in many cases less than half the weight is required to give the same strength. It is also tougher than iron.

Requires no polishing, but dirt can be removed easily by a hot damp cloth.

Can be brazed, hard soldered, welded and cast into moulds.

Can be supplied in **bars** of all shapes, bright rolled **strips, wire and sheets.**

MADE BY

Samuel Osborn & Co., Limited, Sheffield, England

Pioneers in 1870 with MUSHET STEEL and still in the forefront

SOLD IN CANADA BY

Sam'l Osborn (Canada) Limited, Montreal, Toronto & Cobalt

All the Fine Qualities That Good Work Demands

Pratt & Whitney Small Tools enjoy an enviable reputation for excellence that has been well earned in the high production shops of the country. Where stamina as well as exceptional accuracy and precision are required P & W Tools have more than held their own. Our line is complete. It includes taps, dies, milling cutters, reamers, punches, drills, etc., both of standard and special design and in sizes to suit every requirement.

Prompt service is assured at our nearest store, where P & W Small Tools are carried in stock for immediate delivery.

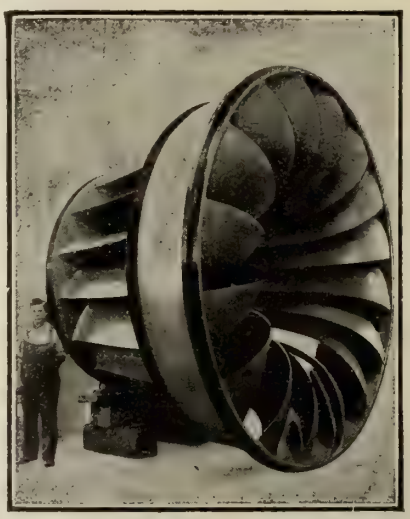
BRISTO
REG. U. S. PAT. OFFICE
PATENTED SAFETY SET SCREWS

SET A NEW STANDARD



The distinctive dove-tail slots or flutes of the "Bristo" safety set screw are one of the features which put "Bristo" in a class by itself. "Mushrooming," for instance, is impossible, and splitting or cracking have been removed from the list of your manufacturing worries. As the wrench turns, the unique "Bristo" design contracts the screw; on releasing the pressure the screw tends to expand—a tremendous gripping factor.

Are You Equipped to do Cylinder Regrinding?

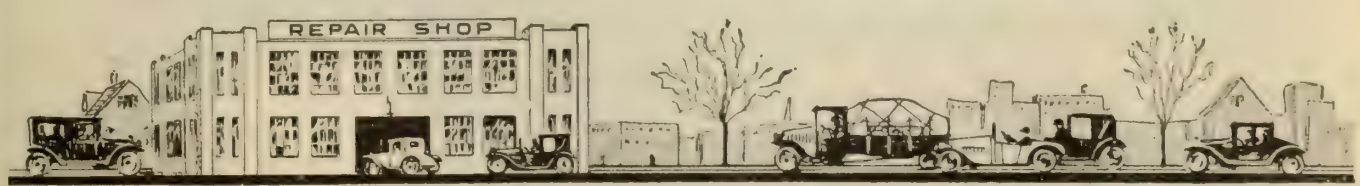
Grinding one of the twin sixes at the Packard Motor Co. of Ontario.

Probably you have been too busy hunting up enough miscellaneous jobs to keep the wheels turning to give much thought to this question. Again, perhaps you considered the automobile was the garage man's game and let it go at that.

The garage may be the headquarters for the majority of ordinary repairs but the machine shop is proving to be a Mecca for regrinding. Already located and equipped with practically all the tools needed, and having operators, who have run grinding machines, and with no reason to cause jealousy or prejudice among the small garages who send in work, by simply putting in a Heald you are ready to start in at once on work that is waiting for someone to come after.

You can command a trade that will keep you as busy as the proverbial one-armed paper hanger and profits will pile up in spite of money tightness. We say HEALD because it is used exclusively in the manufacturing field and thus has an established reputation. There are two types of HEALD CYLINDER GRINDERS, either of which is unapproachable in the field.

The Style No. 55 is simple, moderately priced, self-contained and has a very large capacity and range, easily taking care of all styles and sizes of blocks. Many just going into the regrinding business are purchasing this machine.



The Style No. 65 was primarily built for manufacturers, but scores are buying it for regrinding. When equipped with the HEALD UNIVERSAL JIG, it becomes an ideal machine for this class of work as it is unusually rigid and massive, and has a large number of speeds and feeds.

How much longer will you wait before sending for convincing details?

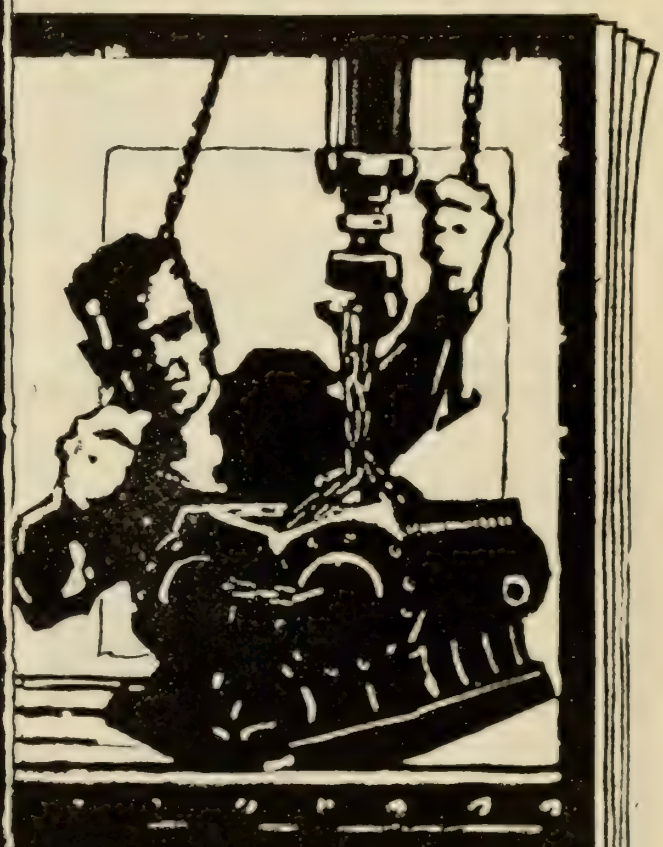
Oakite CleansSteel Tubes 15 Times Faster

A MANUFACTURER now cleans drawn sheet steel tubes with Oakite at the rate of 2400 every five minutes, as against only 152 tubes in the same period with another cleaner.

Judged by the cost per pound, the alkali cleaner formerly used was the least expensive. But with this cleaner only 152 tubes could be cleaned in five minutes. Oakite costs more a pound, but cleans 15 times as much work in the same time. In practice, therefore, Oakite is found by far *the most economical cleaner to use.*

The saving made by this manufacturer shows the importance of practical information on the subject of *Modern Metal Cleaning* such as is contained in the booklet we offer to send you without charge or obligation.

The net result of many years of experience of all sorts of work is given in concise, plain, every day shop language. It is knowledge such as this that has increased production and lowered operating costs for others.



As an expression of what we mean by Oakite Service, we shall be glad to send you a copy of this booklet free Write us today.

Norton Alundum Grinding Wheels For High Speed Steel

Every tool room superintendent and foreman knows what it means to grind high speed steel. He knows how easy it is to "check" the surface, and how much care must be taken by the operator to preserve the tool when grinding.

Whether off hand tool grinding, or automatic tool sharpening, or precision surface grinding of high speed steel, a great deal depends on the proper abrasive, grain, and grade selection.

One Norton Alundum grinding wheel designed for your special job will convince you of its advantages.

Repair Work Should be Handled to Show Profit

It is Useless to Attempt Repair Work Without Suitable Equipment—A Simple Cost System Should be Used, Otherwise Owner Will Never Know Where He Stands—Miscellaneous Repair Jobs

By H. A. WILSON

PROBABLY no class of work that enters a shop presents as many problems, or is as hard to take care of at a profit, as that of repair work. The work, as a class, is not universally popular with the men or the shop owners. Yet there is a certain volume of this work which must be done, and many shops are handling it at a profit. Thus the repair problem is one that will bear careful study.

In the first place it is useless to attempt to accomplish repair work in shops that are not properly equipped. Even a layman can appreciate that no matter how well a shop is equipped for a line of quantity production work, it would be useless for repair work. Thus the first asset one must acquire, in order to execute this type of work, is proper equipment. Probably when we speak of machine shop equipment we think of machine tools, jig fixtures, taps, dies, etc. In the case of the repair shop, however, there is a certain line of equipment that cannot be tabulated or easily described. It is that accumulation of material such as odd taps and dies, special straps and bolts of all kinds, angle plates, planer, vises, lathe and drill attachments, and odd lots of metal in the form of forgings, castings, etc., which have served their purpose in one or more ways on jobs of days gone by.

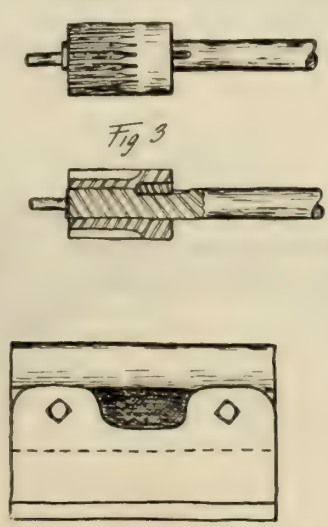
In addition to this list of tangible equipment, the greatest asset perhaps is to have a seasoned organization of mechanics, led by an even more thoroughly seasoned superintendent and engineer, but in addition we must have suitable machine tools. In any specific line of manufacturing, special purpose machines or automatic machinery, play an all-important part, but in repair work we require only the basic type of general purpose tools. In such a category the engine lathe heads the list. There should be at least one tool room lathe of say 12-inch swing with a bed about 6ft. 0in. long. Then there should be an 18 inch heavy duty, and a heavily constructed gap lathe which would swing from 26 in. to 30 in. over the ways. Long beds are useful in the repair shop. Additional equipment in the way of lathes would vary according to the volume of the business and size of the work likely to be handled. A definite recommendation of any stated size or type of lathe, except suggestions in a general way, would be nothing short of presumption, and the figures mentioned above are not to be considered as hard and fast, but rather as approximations.

Thus, we have in a general way expressed ourselves regarding the size of the machines. However, we are very positive and definite in our recommendations of the heavy duty type of machine. A lathe that cannot stand up to high speed practice is a money loser. Hollow spindles, compound rests, double back gears, quick change feed gear boxes, and the screw cutting thread dials are all money savers, as well as the ability of a lathe to pull through a heavy, steady cut.

Value of All Around Capability

All types of drilling machines have their uses, but for all around work it is hard to find a drilling machine that has a wider field of application than the universal type of radial drill press with an arm of at least six feet. The floor plate, block, and pit provide means of taking care of an extremely wide range of work. The purchase of other types of drilling machines will be largely influenced by the general characteristics of the work presented. One or two planers are essential, one for large work and one for medium work, a shaper, a milling machine of the universal type, a bolt cutter, a universal tool and cutter, grinder, and a power hack saw, comprise the list of essential machine tools. Local conditions, of course, and the general class of work available, may cause a somewhat different list of machine tools to be desirable. However, in the general run of repair work the suggested list will fill the bill.

Of course, a large range of small and portable tools is necessary. A wide list of twist drills in both carbon and high speed steels, taps for all standard R. H. threads, a range of straight and taper reamers, with a full range of drill chucks and hand wrenches for same, large and



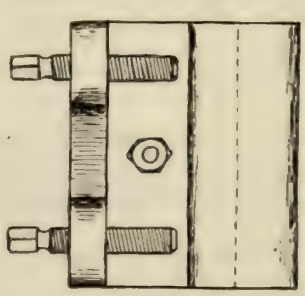


FIG. 1—Simple boring bar holding fixture.

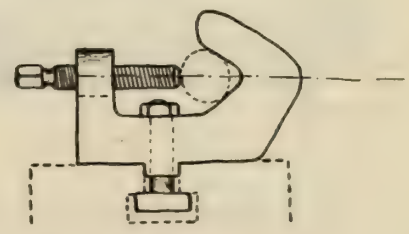

FIG. 3—Showing lathe gear repair.

small face plates for all the lathes, as well as chucks, steady rests, and follower rests, all should be provided. Practically every lathe should have a fixture which could be bolted to the carriage, and which could be used to hold a boring bar, as shown in Fig. 1. A range of boring bars should be provided which would take care of holes of very small diameters up to the largest holes likely to be met with. A large dividing head or indexing head is also very valuable. A good supply of mandrels, parallel blocks, parallel strips, angle plates, clamping bolts, straps, goose necks, babbit mandrels, nuts for "T" slots, hardwood blocks, etc., are among the odds and ends that are invaluable. Thus, it may be seen that the equipment of a first-class repair shop is not entirely purchased, but is accumulated slowly.

The Blacksmith

So much for the machine shop equipment. A repair shop must of necessity be equipped with a first-class blacksmith shop. Generally speaking there should be one or two small forges, and a large forge. An anvil, or two, for hand work should be provided together with a full set of tools and tongs. If work of any decent size is handled, a power hammer of the belt-driven type might be useful. For the very largest work, steam hammers are used. An oil or gas fired furnace fitted with a pyrometer is extremely useful for various lines of work, especially for small tools, gauges, etc. It is quite customary to have a babbitt melting pot and sometimes a brass-melting furnace in the blacksmith shop, provided same is conveniently located to the main machine shop.

If plate and sheet work is done, there should be rolls, shears, punches, riveters, presses, etc., available. Foundry facilities would have to be available, either in the shape of a foundry operated by the shop, or one situated nearby, that was equipped to handle a wide range of jobbing work.

Many jobbing shops are successfully operated without a plate and sheet shop, and some without even a blacksmith shop. The explanation is that these facilities are provided by nearby shops, who cater to the jobbing and contract business. Such connections sometimes work out to good advantage, but they are also frequently the source of a great deal of worry and trouble.

The Problem of Costs

Now that the equipment required has been touched on, we will turn our thoughts to the problem of costs. Quite frequently orders for repair jobs are placed, (after the shop man has looked over the work to be done and has acquainted himself with what is required), at a stated figure, which has been arrived at by an estimate of the time and material involved. In computing the cost of repair jobs a real problem is presented. The layman, however, sees only two items of cost, namely time and material. Now the cost of a repair job has to cover many unusual items. The material costs can be easily taken care of. If one cares to consider all other charges against a job as time, then this item has to cover the labor spent on all special tools and equipment, time actually spent on patterns, cleaning castings, machinery pieces, assembling, testing and gauging, power bills, maintenance, insurance, taxes, interest on money invested in real estate, machine tools, equipment and supplies, advertising, all office expenditures, time spent going to and coming from outside jobs, supervisors, depreciation, lost time between jobs in slack times, cost of small tools and supplies, heating, etc. All these items are pooled together and called overhead expense.

The time expended by men on a repair job is a simple thing to obtain. Thus the overhead charges are the only uncertain quantities in the calculation. These overhead charges are usually expressed as a percentage of the hourly rate paid the mechanic, machinist or millwright. Some well managed shops claim that on average jobs if an overhead of 50 per cent. is charged the shop will break even. Of course these figures would only apply on straight jobs which have no uncertain or complex features, and when the shop was operating at practically full capacity. If a profit was to be made an additional charge would have to be made to cover this item. The average overhead expense of a normal shop working at about full capacity would be from 80 per cent. to 100 per cent. In shops that are carrying a heavy initial investment, or have a large number of highly paid executives the overhead charges will be in excess of the 100 per cent. figure. Speaking plainly, the profit and loss on most jobs can be traced to the degree with which the real amount of overhead expenses have been incurred and calculated.

Source of Profit

The engineering of repair jobs of any size is a very important factor. Some jobs present little or no engineering problems, while others call forth a great deal of skill, in order that they may be successfully handled, and for exceptional skill if they are successfully handled at a profit. Thus in estimating time required for any particular job, the man entrusted with this work must be well versed in shop practice, have an excellent knowledge of the equipment available, and must also have a good grasp of the office end of the business. Usually there is a good margin of time allotted to a contract job, as incidentals will always creep in. Of course, if competition is keen and business rather quiet, the margin of time may be clipped to a very fine point, which is dangerous practice. It is customary for the shop superintendent to know the time alloted to each job and it is his business to keep the time below that figure.

A source of profit to a shop often occurs through the engineering staff devising a new and shorter method of executing the work. Thus in this case a reward is directly received for the intensive application of a man's brains. Profits also accrue from the use of material that has been salvaged from previous jobs and came into possession of the shop for little or nothing.

Profits are often sacrificed when some standard machine or article is placed in a shop for repairs, and an attempt is made to make all the special parts. These special parts on standard articles are practically always made in quantities on automatic and special machines and are sold at a fraction of the cost for which they could be produced in a repair shop. This idea can well be followed up in other ways, and if intelligently applied will become the source of considerable profit. Today, firms standardize and specialize on all sorts of taps, screws, pulleys, hangers, gears, and a multitude of other articles, which are sold at a figure much lower than that for which a repair shop could hope to produce the article. Then too a shop specializing in taps and dies can usually do a special job for a price much lower than that of a repair shop. Thus, to take advantage of all the opportunities offered by outside manufacturing establishments, the repair shop man has to read current

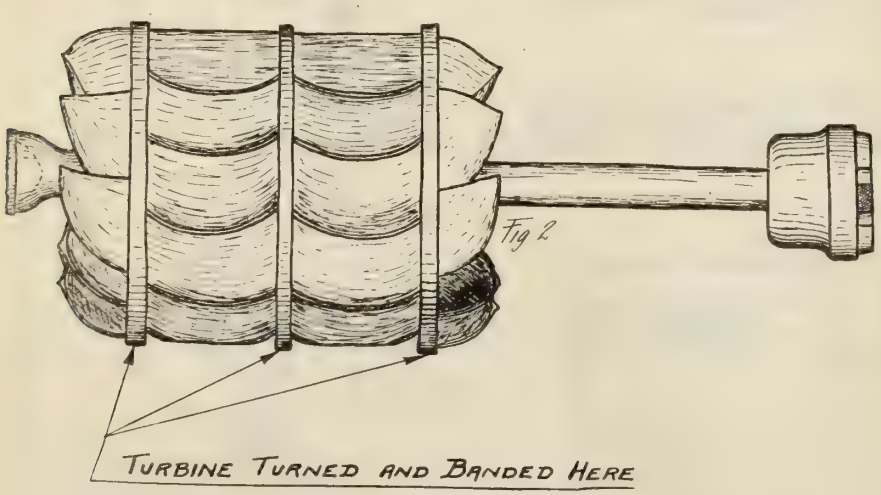

FIG. 2—Repairing a turbine water wheel.

mechanical literature to keep abreast of the times.

A New Practice

In some localities a new practice is becoming rather popular, but it is one that is hardly fair to the ingenious mechanical man at the head of a repair shop. It is the practice of quoting on a repair job on a straight time and material basis. When a job is an outside one such as reconditioning a factory, repairing a steamship, over-hauling a power plant, etc., the party for whom the work is being done, usually takes care of the time of the men composing the repair gang. This is often done by punching the clock in the factory or premises. Of course, time is also checked by a representative of the repair shop. This innovation eliminates any possible controversy as to the actual number of hours spent on a job, but does not enable the ingenious man to directly cash in on his ability, which would be the means of his accomplishing the work in a shorter period of time than some of his less practical friends, it rather tends to penalize him.

Some times financial risks are taken in attempting a short way and a man who carries such a risk ought to be recompensed in a direct manner, just as much as he should benefit financially for having completed a job in a shorter time than it would have required, had some other firm and methods been employed. Of course the indirect benefit the man would receive would be the good reputation he would build, and also the fact that he would be awarded contracts, which under other conditions might not have been received by him.

The time and material basis of handling repair jobs always nets the firm doing the work, a reasonable profit, if the overhead expense can be kept down to a point where the prevailing hourly charge for mechanics is greater than the actual wage paid plus this overhead. In every locality there is usually a standard scale of prices for the services of the mechanic. Thus it is that time and material contracts for repair jobs are never the source of any great profit to a shop.

If real profits are made in the repair business, they are made on jobs which are undertaken at a contract price. It must be borne in mind, however, that money is sometimes lost in this class of business. In large contracts, the various problems are so complex that it is beyond the scope of this article to treat upon them. Thus a few of the simpler examples will be taken up, which illustrate the principles involved in the larger work.

Repairing a Turbine Water Wheel

A manufacturer of a turbine water wheel was called upon to examine a small turbine, of his manufacture, and make an estimate of the cost of repairs. The wheel was examined and it was found to be 21 inches in diameter and was operating a small saw mill. The water was very low at this time of the year, (August) and the cut of the season had been completed some time before. Time did not enter in the proposition, and a thorough examination of the water wheel could be made easily. The wheel, without any accessories sold at about five hundred dollars. The shopman had estimated that repairs, which would make the turbine as good as new, could be made for one hundred and seventy-five dollars. This price was given with the understanding that the owner delivered the turbine to the shop and took delivery f. o. b. cars.

It was found that the turbine gates had been well protected from ice, sticks, and other foreign matter because of a very efficient head rack. The turbine case and runner were of cast iron and the design was of the vertical shaft type. The water wheel was set low in the wheel pit. The bearings, aligning the wheel in the case, were of lignum vitae wood and had been neglected. The result was that the wheel had been rubbing against the side of the case and had worn the bore of the case away almost a quarter of an inch. The diameter of the runner had also been reduced. The lignum vitae bearings were of course worn out. Power was delivered to a vertical shaft, an extension of the turbine shaft, through the medium of a pair of clutch or jaw couplings, no bolts being used. As the wheel wore, this pair of couplings acted as a universal joint. The bearings on the upright shaft were of the babbitted type as they were above water. These were found to be in good shape, as was practically all the other equipment in the mill. The turbine proper, being mostly under water, and out of sight in the wheel pit, had been neglected by careless attendants.

The wheel arrived at the shop. The case was put on a boring mill and was carefully centered and rebored, only enough metal being removed to make a true circle. The turbine runner was put in a lathe, still keyed to its shaft, and the runner was thus also trued up. (See Fig. 2.)

The journal on the top of the shaft was polished and the cup at the base of the shaft, which acted as a thrust bearing, was also trued up and polished. The runner diameter was then carefully calipered and three rings were made in the blacksmith shop from bar iron. These rings were shrunk on the runner. The bands increased the diameter to a dimension somewhat larger than the new bore of the case. Four small holes were drilled in each ring and through into the runner with a 21/64 inch drill. These holes were tapped with ⅜ inch taps and threaded pins inserted. These pins were peaned in place. Then the rings were turned down to fit the new bore of the runner. New lignum vitae bearings were fitted. The old half coupling was next taken off and a new standard half coupling keyed on the shaft. The other half of the coupling was shipped with the turbine, a rough key being provided.

The overhead in the shop in question was figured at 100%. The prevailing rates at the time were as follows; Machinists, 60c.; machinists' helpers, 40c.; laborers, 30c.. blacksmi hs, 55c.; fitters, 60c.; and painters, 50c.

The time and material was shown in the itemized bill which was rendered as follows:—

Time	Hours			
Machinists'...	32¼	at	$1.20	=$38.70
Helpers'.....	9½	at	.80	= 7.60
Blacksmiths' ...	10½	at	1.10	=11.55
Fitters'.....	5¼	at	1.20	= 6.30
Laboring.....	13½	at	.60	= 8.10
Painters'.....	5¾	at	1.00	= 5.75

17 ft.-0 in. bar iron 2¼ in. x ½ in., 8 ft.-6in. bar iron 1¼ in. x ½ in. = 74 pounds at 6 cents or $4.44

1 pair standard jaw couplings = $15.00

2 keys at $1.00 each ..... = 2.00

12 pounds lignum vitae at 35c. = 4.20

skidding..... = 4.00

$107.64

Very little equipment was tied up and only a small number of men thus the job did not interfere with progress on other work. The overhead at 100% was ample and there was a profit shown of approximately $67.36. Of course the jigs and

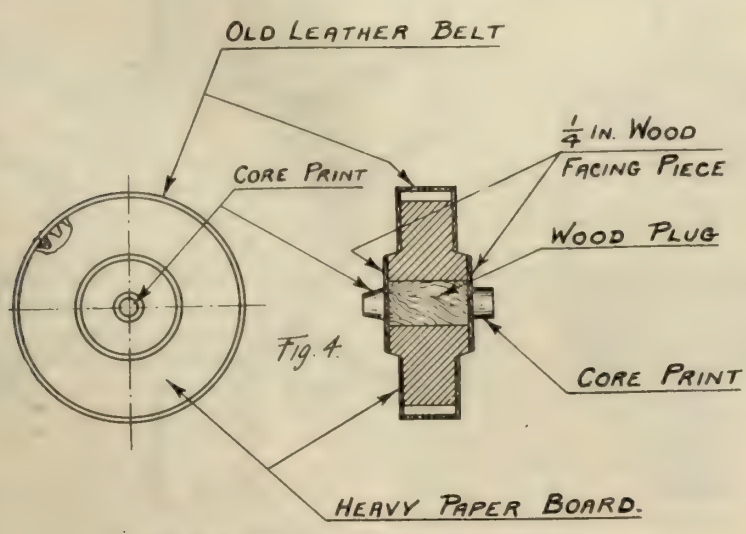

FIG. 4—A quick repair that proved satisfactory.

fixtures used were not charged up to this special job as same had been written off long before the work was undertaken. However, in the overhead expenses a charge for these jigs and fixtures was included, part of which would become profit, and part of which would be absorbed by the care and maintenance of this equipment.

Lathe Gear Repair

Another job, which, although small, was brought to the writer's attention, was a gear repair. This small gear on the back gear shaft of a lathe, had become stripped and rendered the machine useless, except for open belt work. The repair man was called in to see if some change could be quickly effected, as the small gear formed an integral part of the back gear shaft, and to replace it would entail the replacing of the whole shaft, the removing of the large gear from the old shaft, and the fitting of it on the new shaft, as well as fitting the new shaft to the machine. The difficulty was further increased by the fact that it would take ten days before shipment from the factory of the new piece could be made. The repair man made an offer to do the job in thirty-six hours or less. The offer was one which could be expressed as a labor charge of thirty hours. As time was a big factor the offer was accepted.

The back gear shaft was removed. At the repair shop this shaft was placed in a lathe and the remains of the small gear turned off leaving a diameter the same as the shaft. A small shallow key seat to one side of the location of the gear, was cut in the shaft, the work being done on a milling machine. Meanwhile a piece of steel, about one quarter inch larger in diameter than the outside diameter of the gear, was cut from a bar. The length was two inches longer than the face of the back gear teeth. The piece of steel was bored so as to be a driving fit on the back gear shaft and was then placed on a mandrel and turned over its whole face to the diameter of the outside of the teeth of the small back gear. The gear on the mandrel was next placed in a No. 1½ universal tool room miller and the teeth were cut. The shop had a miscellaneous supply of gear cutters and one very close to the proper form was found. A little touching up on the universal tool and cutter-grinder made it just what was required. The gear teeth were cut the proper width to mesh in the gear on lathe spindle.

There was not enough metal between the root of the teeth and the bore to permit of key-seating, so a key-seat was cut in the blank end extension. The gear was bored a few thousandths small so as to be a driving fit on the back gear shaft. Then it was heated and was driven on the shaft and key. (See Fig. 3). A Bristow set screw, on the quarter with the key, was inserted and the job was completed. Eighteen hours were consumed in the work, which was done in a few hours over twenty-four hours from the time the job entered the shop. No overtime was resorted to, and the material charge was small.

Emergency Repair to a Special Machine

During the shell business in Canada, a rather ingenious and quick repair was made to a special machine which was interesting because of its simplicity. A cast iron gear in a special purpose lathe was broken. It was 3.00 p. m. and too late to get another gear cast that day. Production was held up. The gear was of disc design with teeth cut in the rim. Of course the hub was also of somewhat greater depth than the face of the teeth. The gear was 2 inches face and had forty two teeth, ½ inch circular pitch. The outside diameter was thus, roughly 7 inches. The broken gear was removed, as shown in Fig. 4, and leather was wrapped around the outside of the teeth.

The bore was plugged with wood and facing pieces on the hub were nailed to the plug. Card-board discs were placed on the sides of the teeth and the patched up pattern rushed to a brass foundry. The part was moulded and cast just before six o'clock. At seven that evening it was in the shell shop and immediately bored, turned, and keyseated. A miller was put to work and at midnight the new brass gear was in place and the machine running. At seven o'clock the next morning the production for the 24 hours was almost up to normal. The casting of the brass gear blank was paid for by scrap brass accumulated from spoiled brass sockets which were used to some extent in shells. Quick work saved the firm quite a loss, although the circumstances under which this repair job was executed did not permit of the usual checking up as to the actual cost. The result of tieing up that machine for twenty-four hours to forty-eight hours would have run into several hundred dollars.

A repair job in a cement mill that was taken care of in the company's repair shop, by the repair gang of the company was a similar example of money saved. The pulley was of solid design 72 inches diameter, 13 inch face, and was keyed on a 6-15/16 inch shaft. The service to which the pulley was subjected was very severe and thus the design was unusually rugged. The hub, one day, was found to be cracked. The crack led from the corner of the key way. As the pulley was special and was not damaged in any other way it was decided to try to repair it. It was considered that the repair might be accomplished by welding but as there was no reliable welding concern within one hundred and fifty miles, a suggestion offered by the superintendent was made use of.

The pulley was placed on a boring mill and the hub turned on each side of the arms. Heavy steel rings were shrunk on the hub, as shown in Fig. 5, and the pulley returned to service. It ran for several years afterwards and was still in commission when last heard of. Here again is an example of quick action and ingenuity which enabled repairs to be made which kept a plant operating and saved large sums indirectly as well as being of a direct and immediate source of saving money.

Jaw Couplings As Universal Joint

A few years ago a rather peculiar job was undertaken by the writer. A small tramp barge had been purchased by a couple of men of limited means. The vessel was of wooden construction and bore unmistakable signs of age. She was drydocked and repaired, after a manner which was considered suitable for use on the minor inland waters. Difficulty arose in the shaft bearings. Bearings were continually heating and in one bolted coupling, bolts were always breaking. The shaft had been lined up several times and shortly the trouble appeared again. It was clear that with various

(Continued on page 26)

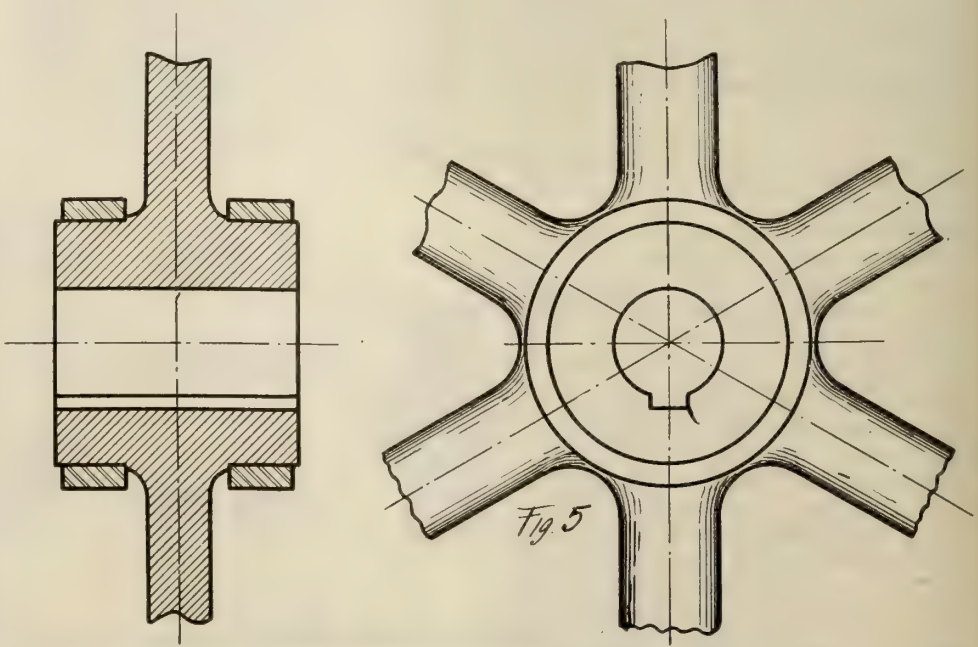

FIG. 5—Showing how pulley was repaired.

Salvaging Machine Shop Waste Important

Method of Segregating Chips, Turnings and Other Scraps Affects Value—Boxes and Packing Materials Can Often be Utilized in Plant—Lubricating Oil and Cutting Compound Should be Reclaimed

*By J. A. SMITH

THE TERM "salvaging" has become a world-wide slogan. Industrial managers are studying operating conditions as never before in the history of business, and among the various phases of the subject which relate to the reduction of operating expense, the salvage of factory wastes comes in for a large measure of attention.

First consider the question of salvaging metal wastes—for every factory in the country manufacturing a mechanical or semi-mechanical product produces metal scrap of one kind or another. It is essential a system be set up whereby the various grades of metal chips and turnings be kept separate in the shops during machine processes in order to save time and labor sorting and segregating in the scrap or salvage department. Non-ferrous metals should always be kept separate from steel and iron. When the parts machined consist of a non-ferrous metal with steel or iron, the chips should be run through magnetic separators.

In some of the larger industries, chips and turnings are pressed into briquets of suitable cupola size, but this practice has not become general throughout the country, and is carried on chiefly where the tonnage of chips and turnings is normally large. The process results not only in higher market value, but also in a material saving in transportation charges. Sheet-metal punching scrap, metal strips, trimmings, wire, etc., should always be put in bundle form and in cupola size before being loaded for shipment.

Miscellaneous Scrap

All the various classes of miscellaneous scrap metal, such as cuttings and trimmings from bar, rod, and heavy sheet stock, small castings, forgings, and solid pieces of every kind, should be accumulated in separate containers in the shop, for this class of scrap has a higher market rating than is obtained for chips and turnings.

Laboratory processes often are productive of valuable wastes in the form of metals such as tungsten, molybdenum, etc., or in various chemical residues which may through conversion or combination become the basic elements of new preparations and compounds.

There is a wide variety of miscellaneous wastes which require attention, and in this field a great amount of salvage work can be profitably done. Lumber, boxes, rope, rubber, fiber, cotton and woolen fabrics, cotton waste, paper insulation materials, chemicals, etc., constitute some of the items which can be salvaged with profit in modern industry. Incoming boxes can be repaired and put in shape for future use either for storing materials, or as tote boxes in the shop. When too large to be suitable for these purposes, the lumber can be utilized for repairing and making tote boxes, temporary platforms, stagings, concrete forms, etc.

The salvaging of lumber and making of boxes from this second-hand material in some of our large industries represents a saving of many thousands of dollars yearly in the purchase cost of new lumber. Even sawdust, usually considered of little value, can be used for the packing of porcelain and similar products, and the finer grades for the drying of metal parts in the dip shop. There is scarcely an item which can be named in the list of industrial wastes that has not some value either in its present state, or in the production of raw materials for the manufacturer's use. Even what is known as shop refuse may be burned in a destructor plant under boilers, and produce steam for heating and manufacturing.

Segregating Metals Is Important

A careful system of segregation is essential in the salvaging of metals, as well as of all other kinds of factory wastes, and this should be carried to the highest standard consistent with local conditions and without defeating the purpose of securing the highest market prices by undue expenditure for labor and equipment. It is well to have all scrap weighed and credited to departments for the two-fold purpose of correct accounting and inculcating an interest for salvage work in all department heads.

But salvage work must be carried into other branches of shop activity, such as maintenance of property, repairs to machinery and tools, handling of stocks, and upkeep of all the various classes of small tools, high-speed steels, etc., and here is where the expenditures begin to mount up to vast sums during the course of a year.

It is essential, therefore, that systems be set up whereby all these items of maintenance receive the most careful scrutiny and expenditures will be adequately limited and controlled. Systems must be set up governing the distribution and repairs of the various classes of small tools so that consumption of these will be regulated within certain defined limits of economy and efficient service, in accordance with production requirements in the shop.

It is good practice to make regular monthly inspections of machine tools and equipment, and make a record of the same, in order that repairs may be made promptly at a minimum of cost before the damage becomes more serious or breakdown ensues with increased repair expense and added delay to production. The record is valuable as showing the relative cost of maintenance and relative life of service of various makes of tools. It is often good economy to replace a tool showing high maintenance cost with a new tool of some other make and thus save expense and delays to production. In all cases of replacements and repairs, valuable parts should be salvaged and made use of on other jobs of repair work, wherever practicable.

Small Tools

In the supply of small tools to the shop much can be accomplished in the way of reducing expense by efficient methods of distribution and collection. A system of regular inspection of toolrooms, tool cupboards, benches, and areas around machine tools should be established. Tools not needed for immediate or current use should be cleared up promptly and returned to stock, and those needing repair put into shape. This is particularly important in the case of high-speed steel tools where the cost is relatively high by comparison, and a single idle tool may represent a good many dollars of tied-up capital.

Nearly all the various small shop tools, such as wrenches, vises, hammers, drills, cutters, pliers, files and numerous others can be repaired to good advantage and thus be made to give greatly lengthened service. By a properly organized system of distribution and collection the inventory of tool stocks carried may be greatly reduced, expenditures for new tools curtailed, and those in use in the shops kept more constantly in active service.

Lubrication of Tools

The subject of lubrication both of machine tools and of cutting tools affords opportunity for valuable reduction in the operating expense of the shop. With modern storage equipment and facilities for distribution to the shops, also proper feed pipes and oilers for regulating the supply to tools, a material saving in consumption of oils and cutting compounds can be made. Selection of oils is most important, and this should always be made with a view of reducing friction load on bearing surfaces and of keeping tools properly tooled and lubricated during the process of cutting, and not primarily in reference to cost.

*From a paper presented at the annual meeting of the American Society of Mechanical Engineers, New York. The author is general superintendent, General Electric Co., Schenectady, N. Y.

Valuable work has been done in recent years in the substitution of mineral oils and mineral lard oils for pure lard oil in a variety of processes where formerly pure lard oil was felt to be necessary. In fact, a heavy-body mineral oil of correct specifications will do the greater percentage of jobs commonly done with lard oil without any material increase in consumption, and with greatly reduced cost. A high-grade light-body mineral oil will also do many processes, such as turret-lathe work, milling high-carbon steels, etc. Soluble cutting compounds also have their place in machine-shop practice, and their use in a great variety of processes, such as drilling and milling, plain lathe work, cold cutting, etc., results in greater economy than can be secured with oil.

Attention needs to be given to the handling and distribution of oils in order to avoid waste. Machine tools should be equipped with proper tanks, drip pans, and aprons, in order that nothing may be lost. Reclaiming oil from reduction parts and from ships and turnings is a part of the salvage work of every up-to-date factory. Much talk is heard on the subject of reducing inventory, and it is essential that the work be carried forward intelligently and earnestly. The present is the time to make thorough investigations of every department and storage space, and to gather all surplus or idle materials and make effort to put them into service, or otherwise dispose of them to advantage. Analysis must be made of the methods of handling and distributing materials in order to establish improved systems, reduce labor, and avoid delay or damage.

Special attention should be given to cutting raw materials to required dimension or multiples of required dimension in order to save waste; and to the salvaging of all left-over pieces and parts for further use in some portion of the factory, wherever practicable. The central storehouse should act as a clearing house for this purpose and thus aid in the general work of salvaging.

The Human Element

The human element enters into salvage work, as into other industrial operations. If department heads and employees as well, can be interested in saving everything of inherent value, a valuable service in helping to re-establish industry will be performed. Not only industrial managers, but the public as well, are more interested in this most vital of human problems. One of the large industries salvages annually, in normal times, more than 80,000,000 pounds of factory wastes. The railroads also have caught the spirit of thrift and are establishing new practices which are showing greatly improved conditions as regards operating expense. The country at large in a recent year saved scrap, consisting of metals, papers, rags, wool waste, cotton fabrics, etc., aggregating more than $1,500,000,000.

In the next few years industry will be called upon to bear a large portion of the burden in the vast and arduous work of reconstruction. Engineers and managers should be strongly imbued with the vital principles of economy and thrift, and with the importance of greatly increased effort along the lines of salvage work. The question of profit must not always be a deciding factor, but a broader view of saving everything which may be of value to others in the production of raw materials or finished fabrics. The manufacture and supply of raw materials depends so often upon the supply of various kinds of scrap and waste that it is most essential consideration be given to the country's needs as a whole. Indirectly benefit will be derived through reduced cost of the raw stocks purchased.

Each Individual Can Help

No appeal to the manufacturer to save the waste products of industry can be made too forcible or too strong, nor can too much emphasis be laid upon the necessity for every individual joining earnestly in this work. Every pound of junk saved and turned over to the junk dealer in the end reaches the great melting pot, and finally the marts of trade, in the form of raw materials to be of definite value to some one; and that one, incidentally, may be any one engaged in the profitable manufacture of fabrics which serve a public need.

The nations of Europe, through the exigencies of the war, were forced to carry on the work of salvaging to its greatest limit in order to sustain the people at home and the armies in the field; and now, during the period of reconstruction, they appear to have doubled their efforts and to have gone beyond this limit in the struggle to rebuild government and business and industry on a stable and enduring basis. In America the people are gradually becoming more and more aroused to this big problem both in public and private life. The vital importance of practising the simple precepts of economy and thrift and of guiding all actions both in business and private life to that essential end is needed.

A permanent reclamation service, fostered and maintained by the national government as other public services, is needed. Through this office practical appeal could be made to the governors of states to mayors of cities and presidents of villages, and through these latter to the heads of boards of trade and to public-spirited citizens, to cooperate in the work of saving the nation's wastes.

Through this channel also could be disseminated much useful knowledge and instruction relating to the work of reclamation, which would thus reach in a helpful way not only the populous industrial centers but the outlying districts as well, and by this means bring about a widespread, concerted action for the public good. No one may attempt to predict the full extent of the value or the aggregate return of such a movement to the government and country at large.

Still another phase of salvage work which is distinct and apart from the field of salvaging metal scrap and other factory wastes, is saving of time and of human effort, the harboring of mental and physical energy, and the devoting of all efforts to highest purposes and highest aims. Profitable manufacturing requires the building up of organizations both in offices and in the factory with a view of concentrating directive effort, eliminating duplication of orders and instructions, establishing unity of purpose, system in method of procedure, and co-operative effort on the part of all employes, whether serving in official capacities or in the lower grades of mechanical and physical labor.

It is essential departmental forces be organized in such manner as will secure systematic control of all the functions of labor and consumption of materials, and the keeping of manufacturing expenses within the budget provided for conducting shop and office work. Organizations must be built with a view of attaining the highest standards possible, in order to re-establish business on the high plane of influence which it must always occupy in the successful upbuilding and support of the government and nation, and in the permanent establishment of the normal pursuits of industry and peace.

LARGE CRANK SHAFT

Something approaching a record in large crank shafts was recently achieved in a British engineering works. This shaft was constructed for a large marine engine. It measures nearly forty-three feet long and weighs fifty tons. Much more notable than its size, however, was the accuracy with which it was finished When the shaft was inspected the error in the total length was only eight one-thousandths of an inch, while the maximum error in all the bearings did not exceed twelve ten-thousandths of an inch.

HOURS TO MINUTES

What are you doing in your firm, to reduce hours to minutes?

This is one of the vital questions that measures your efficiency. Nearly all profits and high wages and low costs depend upon reducing hours to minutes.

For instance, a typewriter with a quick typist writing sixty words a minute, reduces an hour to twenty minutes.

A steam shovel reduces an hour to three minutes, as it does the work of twenty laborers.

A printing-press, continues Efficiency Magazine, reduces an hour to perhaps one-fortieth of a second, as it would take forty men one hour to write one copy of a ten-page newspaper which a press prints in a second.

In these days of high cost it is the time element that makes you or breaks you.

Our one main hope of success is in reducing hours to minutes—in getting more work done in less time.

The Problem of Efficient Power Transmission

Unfortunately This Important Production Factor Has Not Received the Attention it Deserves—Friction Causes Largest Percentage of Loss—Charts And Tables Showing Different Conditions

*By G. C. V. HEWSON

THE EFFICIENT transmission of power is a problem which, unfortunately, has received but scant attention in all but a very small percentage of the mills in Canada and the United States. Even in plants being laid out and built at the present time, the transmission question seems to be receiving no consideration, and engineer concerned apparently believes, that for this work, anything is good enough, and that if he can economize by buying second hand material so much the better.

It would appear, therefore, that the general engineering world has not made much progress in this regard in the last ten years, for the same state of affairs was deplored by Professor Unwin, one of the foremost authorities in machine design, in the last, or 1912 edition of his text book "The Elements of Machine Design," Part 1. On page 261 of this volume the following statement is made:

"In any large factory, the shafting, with its couplings, pulleys and gearings, forms a very important, costly, and power absorbing part of the machinery. Although great attention has been paid to the economical production of power, and its economical use in machines, the intermediate transmission is sometimes barbarous in arrangement and shows great neglect of any study of conditions of efficiency. In different machine shops it has been found that the power required to drive the shafting varies from 15 to 50 per cent. of the whole power employed."

That the loss of power through friction, in line, and other shafting, is of serious proportions has been amply demonstrated by various tests carried out from time to time. It has been stated that at Sir Christopher Furness, Westgarth and Co.'s Engine Works, Middlesborough, England, in one shop where two long lines of shafting and a comparatively small number of tools were used, the loss was 75.6 per cent. and that in two other shops it was 59 and 42 per cent. Truly a remarkable state of affairs.

No. of Installations Tested	Class of Industry	Max. H. P. per brg.	Min. H. P. per brg.	Average H. P. per brg.
6	Stone working	0.245	0.124	0.191
7	Wood working	0.318	0.015	0.117
25	Clothing mfg.	0.037	0.010	0.027
50	Machine shops	0.237	0.025	0.066
100	Various	0.321	0.015	0.119

Further light is thrown on the subject of transmission friction losses by the above table taken from an article "Friction of Line Shafting" by C. A.

* Engineer with S. K. F. Co., Toronto.

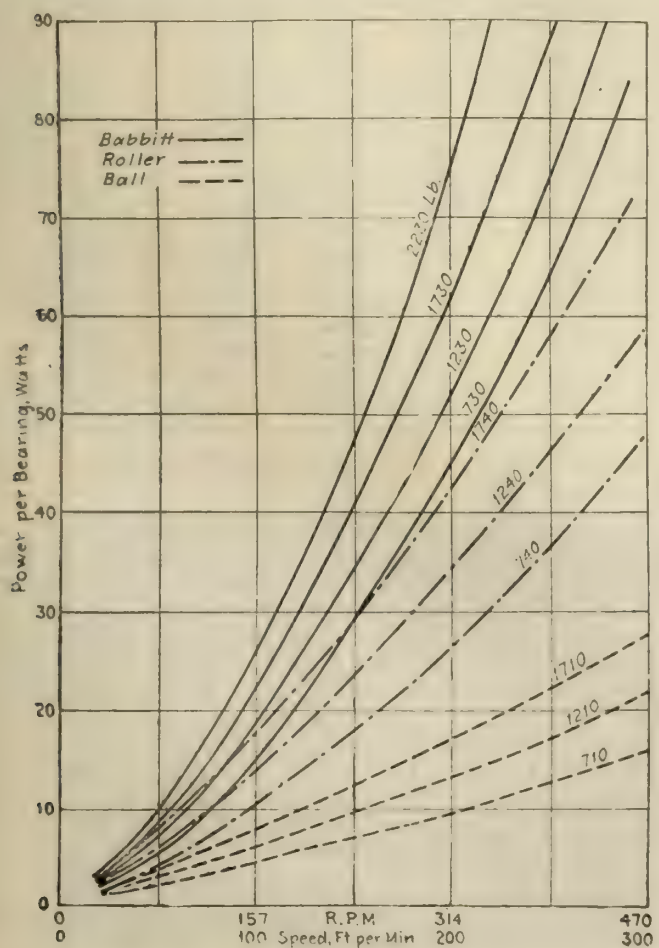

FIG. 1.

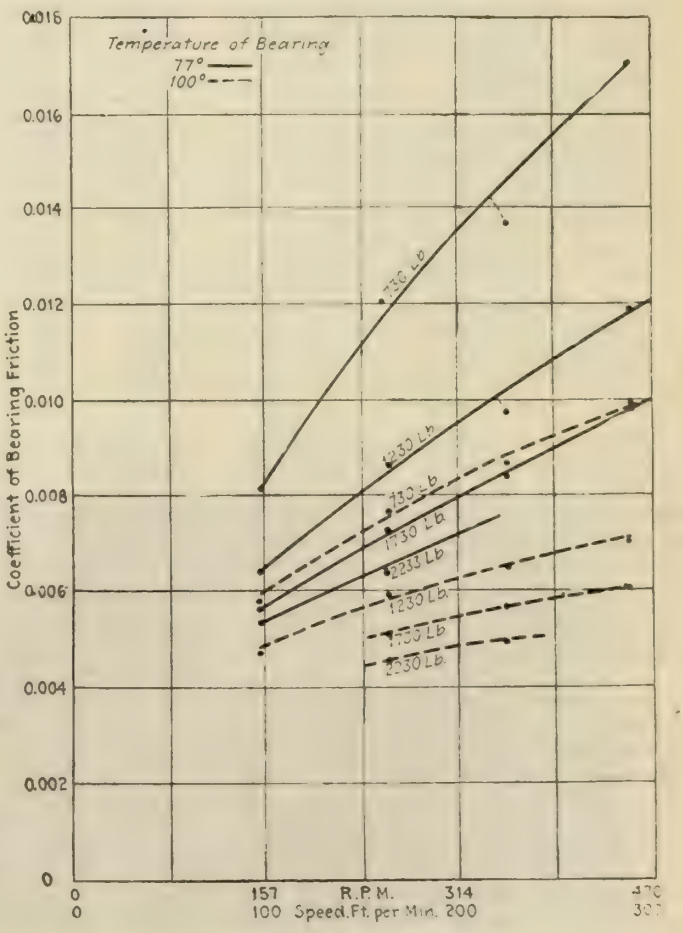

FIG. 4—Power Consumption Chart.

Graves, in "American Machinist," and giving the result of tests carried out on 188 installations.

Classified According to Industry

Classification according to size, the following table gives average h. p. per bearing:

No. of Bearings	Size of Shaft	Average R.P.M.	Max. H.P. per brg.	Min. H.P. per brg.	Average H.P. per brg.
66	15/16–1	428	0.052	0.010	0.036
706	1 – 1/8	382	0.079	0.016	0.033
37	1 – 1/4	425	0.119	0.040	0.062
492	1 – 1/2	392	0.193	0.035	0.089
155	1 – 3/4	218	0.113	0.029	0.078
409	2	242	0.300	0.028	0.133
21	2 – 1/4	264	0.321	0.124	0.257
83	2 – 1/2	243	0.300	0.085	0.255

While the above figures are of considerable interest as showing the conditions that obtain, they do not exemplify the true significance of the results as clearly as the following table covering the bearing losses in thirteen different industries and containing a column showing the percentage of total input power that is required to drive the shafting:

INDUSTRY	Line shaft in feet	R. P. M.	No. of Bearings	No. of Belts	No. of Counters	No. of Machines	H. P. to drive Machine	H. P. to drive Shafting	Percentage to drive shafting
Wire drawing and polishing	1130	170	115	89	69		243	157	39
Steel stamping and polishing	580	200	68	28	27	18	17	57	77
Boiler and machine work	1530	150	46	53	47	43	13	25	66
Bridge machinery	1460	110	142	92	79	69	11	48	81
Heavy machinery work	1130	190	110	141	96	68	48	64	47
Heavy machine work	1065	180	114	192	152	123	77	91	54
Light machine work	784	135	101	217	133	250	20	21	51
Manufacturers small tools	500	114	58	335	314	313	34	40	54
Manufacturers small tools	900	175	102	217	202	258	23	24	52
Sewing machines and bicycles	2490	150	274	521	403	454	82	108	57
Sewing machines	1470	160	184	484	435	179	33	74	70
Screw machines and screws	1800	180	180	486	392	428	127	114	48
Steel wood screws	674	175	96	131	89	392	100	17	15
Manufacturers' steel nails	988	200	74	187	175	184	50	46	50
Planing mill	165	267	19	45	40	53	11	28	73
Light machine work	275	175	27	48	27	30	4	4	49

Examination of the last column of the above table reveals the fact that from 15 to 81 per cent. of the total power required to operate the plant is absorbed in line shaft friction. The industries given, while by no means complete, are at the same time representative and indicate the ridiculous state of affairs existing in probably every line of manufacture.

For instance let us consider flour milling, a branch not covered by the above data. Taking the industry as a whole, it is safe to assert that more than one-half of the total power consumed is wasted in bearing friction and that of the energy delivered by the motor, less than 50 per cent. is available for converting the wheat into flour. Considering the type of mill, it is a matter of record that the minimum friction load is about 45 per cent. and the maximum about 65 per cent. of the total power consumed, with the mill running empty, and not taking into account the immeasurable friction that is added to the original friction load when the feed is turned on.

The absurdity of a condition, such as the one just outlined, must be apparent to every thinking man. Of what use is it to develop the efficiency of a prime mover to the really remarkable figures that have been obtained in recent years, for instance 93 per cent. in large water turbines, and to perfect the driven machine or machine tool to an efficiency close to 100 per cent., if the two are to be linked together by a transmission system whose efficiency may be as low as 15 per cent? Clearly a ridiculous idea. But worse than the ludicrous result is the pathetic fact that clever men can use so little logic in dealing with these matters.

Obviously, the only solution is an anti-friction bearing of maximum efficiency; and to fulfill this condition the ball bearing is most eminently suited. No more convincing evidence of this fact can be given than by outlining the results of a series of tests of the comparative friction of three types of lineshaft bearings, carried out at the University of Wisconsin, by Professor E. R. Maurer, (Professor of Mechanical Engineering) L. E. A. Kilso, (Instructor in Electrical Engineering,) and four senior students doing research work. These tests were made in order to ascertain definitely the relative and absolute amount of power required to drive a specially constructed lineshaft, carrying given loads at certain known speeds of revolution, when supported successively by three different types of shaft bearing, and to determine coefficients of friction for each type. The three types were tested, (a) a ball bearing, (b) a ring-oiled babbitt bearing of the following composition, lead 86.1 per cent., antimony 11.9 per cent, and tin 2 per cent. The last type tested was a roller bearing.

The coefficient of friction for ball and roller bearings was computed, just as for babbitt bearings, from the formula.

$$f = \frac{531 \text{ (watts per bearing)}}{\text{IIdn (load per bearing)}}$$

where "f" is the coefficient of friction, "d" the shaft diam. in inches, and "n" the revolutions per minute, one watt being equal to 44.26 x 12 or 531 inch. lbs. per minute. Figs. 1, 2 and 3 show the coefficient of friction speed-curves

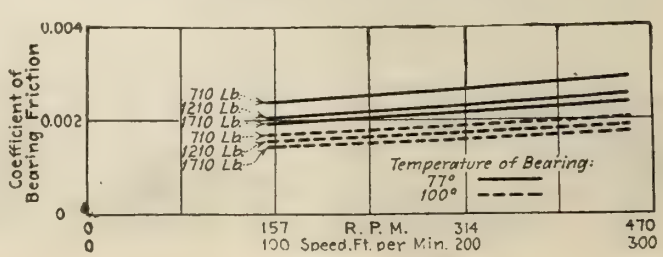

FIG. 3

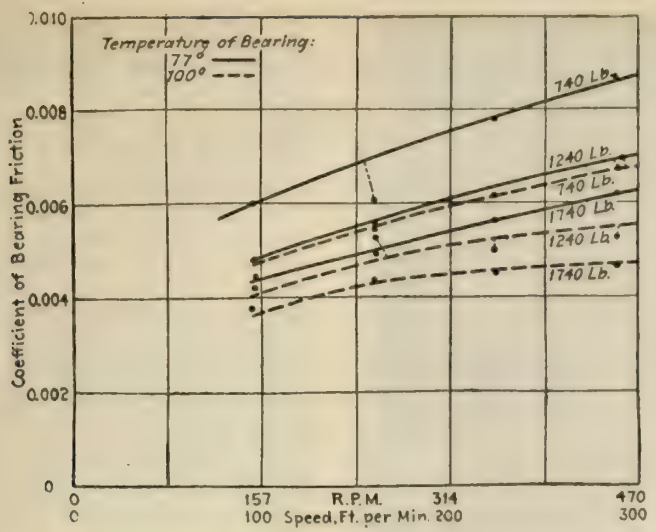

FIG. 2

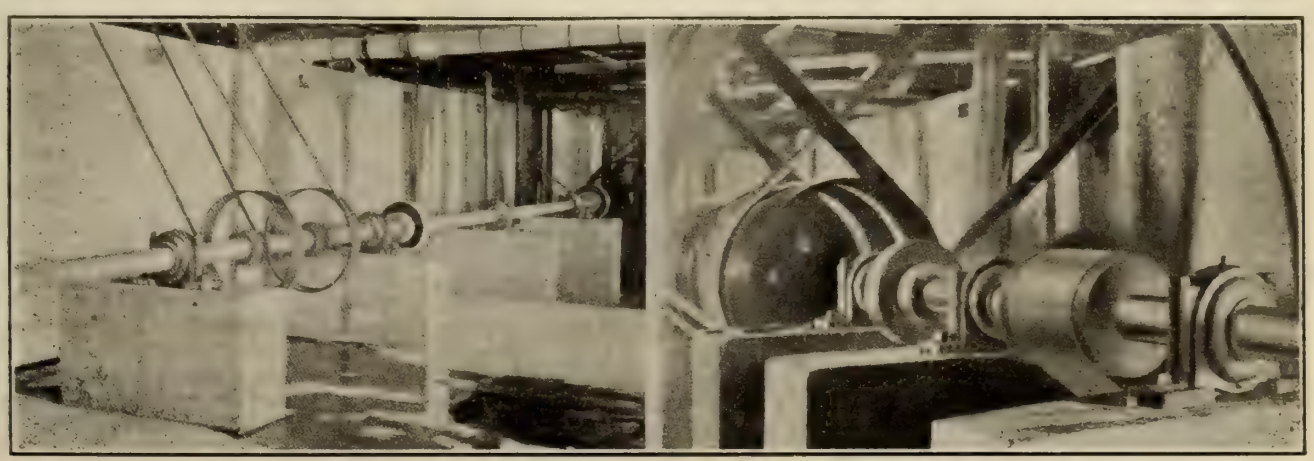
for babbitt, roller and ball bearings respectively, at 77 degrees and 100 degrees temperature. Analysis of these curves reveals the fact that the coefficient of friction for a babbitt bearing at low speeds is about 30 per cent. higher than for a roller bearing, and 200 per cent. higher than for a ball bearing. The babbitt coefficient increases very rapidly with speed, especially on light loads. The roller bearing coefficient increases much more slowly, while the ball bearing coefficient is almost constant over the entire speed range. This last fact is of importance because it means that the friction load of ball bearing transmission is constant at all speeds.

An important point, not shown on these curves, because the first readings recorded were considerably above zero, namely 157 R.P.M., is the large coefficient of friction of a babbit bearing at the actual moment of starting, that is, between zero and ten r.p.m. This value is extremely high, due to the fact that the oil is squeezed from between the journal and box while the shaft is at rest, and the coefficient of friction is that of steel on babbit until a film of oil is formed between the surfaces. In a roller bearing, the coefficient has only a slightly higher value at the moment of starting than it has after the shaft has commenced revolving, while in a ball bearing the co-efficient is practically the same at starting as at any time later. This point is of the utmost significance since it means that a smaller motor can be used to start a shaft equipped with ball bearings than to start a shaft carrying the same load in babbitt boxes.

Fig. 4. compares the power consumed by friction in the babbitt, roller and ball bearings at 77 degrees Fah. Each curve gives the power required per bearing, of the kind indicated, to run the shaft under the load and at the speed specified. The figure shows that the power for the babbitt is higher than for the other bearings, and that the power for rollers, is higher than for balls. The excess of power for babbitt over rollers and rollers over balls increases with an increase in speed for all loads. The following table shows the relative amounts of power consumed in friction by the three kinds of bearings at the speeds and temperatures indicated. The relative numbers are based in each case on the average power for three loads: 710, 1210 and 1710 lb. for ball bearings; 740,1240 and 1740 per roller bearings; and 730, 1230 and 1730 for babbitt bearings.

This table is not intended to give more than a few figures, taken from the curve, so as to present a general idea of the relative power consumption of the three types of bearings.



From the above it is readily seen that two important results are obtained by the use of ball bearing transmission. The actual frictional load is reduced to a minimum at all speeds of operation, and the size of the motor necessary to start any given load is decreased. There are however, other features which, while though not so important as the two just mentioned, have a decided effect on the general operating efficiency of the plant.

A ball bearing equipped line shaft can be operated at speeds far in excess of a shaft on plain bearings. By directly connecting the shaft can be run at motor speed. In a woodworking plant, the advantages of such a drive are obvious. High speed countershafts are eliminated and with them is eliminated one of the most frequent sources of trouble. Also, the smaller the number of countershafts, the fewer the belts required, with the consequent reduction in first cost and maintenance. Such a drive is illustrated in the drawing Fig 5. A practical example is shown in Fig. 6, which is a photograph of a heavy roll stand drive direct connected to a large motor in the plant of the Quaker Oats Co. at Peterborough.

If the speed of the line shaft is increased to two or three times what it formerly was, the size of the pulleys may be correspondingly reduced so as to give the same rim speed as before. For instance a 10 inch pulley at 650 r.p.m. has the same circumferential

Relative Amounts of Power Consumed In Friction

Bearings	100 feet per minute		300 feet per minute	
	77 Deg.	100 Deg.	77 Deg.	100 Deg.
Ball	1	1	1	1
Roller	2.2	2.5	2.7	3
Babbitt	3	3.6	4.5	4

FIGS. 7 and 8—For reference to these photographs see text.

FIG. 6—Heavy roll drive direct connected to 450 h.p. motor

speed as a 25 inch pulley at 260 r.p.m. A considerable saving in the cost of pulleys can thus be effected. Or, when operating at increased shaft speed, by keeping the main line pulleys close to their former diameters (thereby increasing the rim speed,) narrower and lighter belts can be used.

The advantages of applying ball bearings to countershafts are quite as great as those obtained by applying them to main line shafts. There is probably no piece of mechanism, of the same size and cost, in the machine shop which causes as much trouble as the average counter. This trouble can be completely eliminated by the use of ball bearings regardless of the speed at which the shaft is operated. The belts can be run slacker, due to the small friction load, resulting in a decreased maintenance cost. The remarkable saving that can be effected under certain conditions was brought to the writer's attention about a year ago. A certain firm in Toronto had a reversible countershaft, which destroyed, on the average, three sets of belts per year. They equipped this counter with ball bearings which cost them $72.00. At the time of the writer's visit, which was two years after the ball bearing installation had been made, they were still using the same set of belts they had put on at the time the bearing change over was made, and were in perfect condition. As the belts cost them $38.00 a set, and they had been using three sets a year, they saved the cost of the ball bearing equipment in less than the first year.

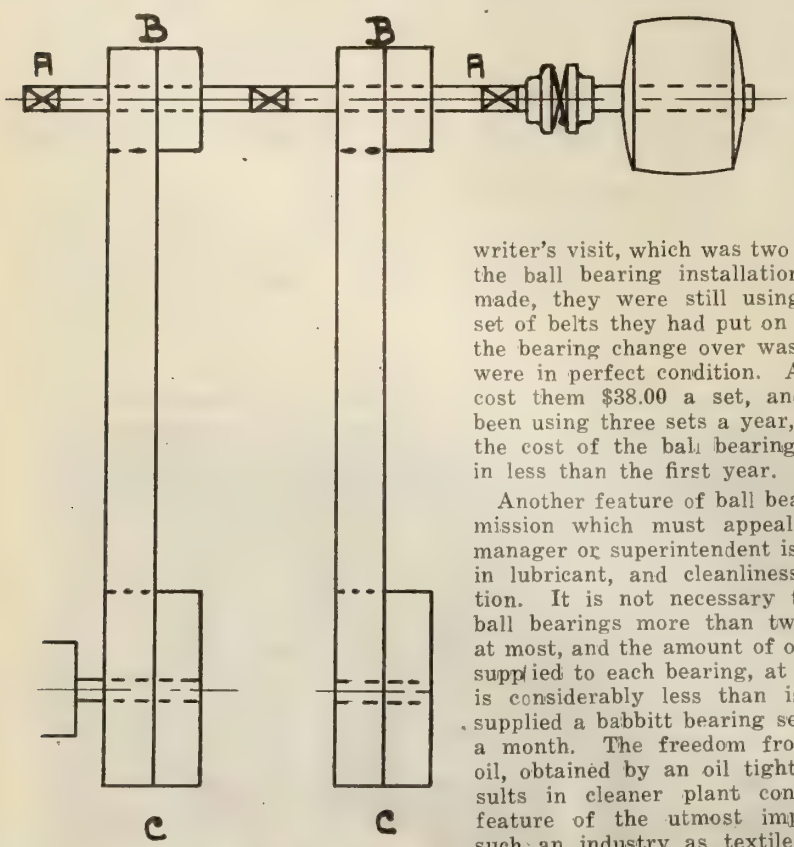


FIG. 5—A direct connected shaft

Another feature of ball bearing transmission which must appeal to every manager or superintendent is the saving in lubricant, and cleanliness of operation. It is not necessary to lubricate ball bearings more than twice a year, at most, and the amount of oil or grease supplied to each bearing, at such times, is considerably less than is generally supplied a babbitt bearing several times a month. The freedom from dripping oil, obtained by an oil tight casing results in cleaner plant conditions (a feature of the utmost importance in such an industry as textiles,) and reduces the fire hazard.

Owing to the fact that the bearing is enclosed in a dust proof housing, it can be operated satisfactorily in plants where dust and grit conditions in the atmosphere are such as to quickly bring about the destruction of the unprotected plain bearing.

Before leaving the subject the writer would like to correct an erroneous impression still held by many users of power, namely, that ball bearings cannot be used on heavy drives. Figs. 7 and 8 are photographs showing a 5 15/16 inch line shaft, 100 feet long, mounted on ball bearings. This shaft is driven by a 28 inch belt and transmits 375 horse power. In spite of the great weight of the shaft with its pulleys, when the belts are off, the entire length can easily be turned by one man. Further comment is unnecessary.

REPAIR WORK

(Continued from page 20)

types of cargo, and with varying quantities of the same, the boat strained sufficiently to throw the shaft out of line. One thing was certain, a rigid bolted coupling would never do. The trouble was reduced a great deal by simply substituting a pair of jaw couplings of heavy design for the flanged and bolted couplings. This was done at a moderate cost and gave the engine on the old craft a fresh lease on life. The thrust was taken care of in such a way that this expedient did not interefere with it.

Another job that was somewhat unusual and yet simply disposed of was the case of a large 60 inch x 60 inch planer. The shop in which this planer was located did quite a flourishing business in cast iron foundry flasks which were used in an up-to-date factory for moulding bath tubs. The copes, cheeks, and drags, had to be planed square and to thicknesses within a few thousandths. This, the planer would not do. It was practically impossible to place a cope piece on a drag and avoid a slight rocking. It was only a few thousandths but was great enough to permit of the rejection of the pieces. It was found when the machine was checked over that internal strains in the castings were blamed as well as the theory that the parts had been clamped in a manner so as to distort them. These theories were investigated and were found wanting. The trouble still remained. The firm offered a premium to anyone discovering the trouble.

The man who received the premium discovered that the machine had recently been reset and that when checking up the setting only ordinary levels and measuring instruments had been used. Thus he felt sure that had precision instruments been used it would have been found that the machine was not set properly. He used these instruments and found the extreme end of the bed had settled slightly. He introduced thin shims under the supporting pads and re-planed the table and the trouble had disappeared. His work took only a few hours and it netted him a nice profit.

The Prevention of Freight Loss and Damage

Railways Have Recently Taken More Progressive Steps to Prevent Losses to Goods in Transit—Loss and Robbery Are Two Important Factors—Men Can Accomplish Much by Holding Experience Meetings

*By JOSEPH MARSHALL

PRACTICALLY all railways have taken more or less progressive steps to prevent loss to goods in transit with splendid results. However, the individual departments have not been able to check loss in goods which, in order to reach their various destinations, have to be routed over several lines. In order to attack the problem from this angle the association with which I am connected was formed, and we are securing the support and co-operation of practically every road in the U. S. A. and Canada. Figures tabulated by our association show that $125,836,948.00 was paid in claims by the Canadian and American roads during 1920.

The average man would hardly believe that a sum equal to what it costs the railroad to secure its traffic is paid out for mishandling after it is secured.

Loss and damage exceeds account of the superintendence in transportation. It exceeds the cost of dispatching trains and all station supplies and expenses. It will more than pay the wages of all yard enginemen. It will almost pay the fuel bill for the yard locomotive. It will pay the yard enginehouse expense, plus the yardmasters and all the clerks.

It costs twice what bureaus, advertising and law expense cost during 1919 and half as much as the bill for ties. It would more than pay the cost of supervision of maintenance of ways and structures and maintenance of equipment combined. It will almost pay the bill for rails. It will come within a half million dollars of paying the tax bill. It will pay the insurance bill for every general department, and you could add the entire stationery and printing bill for all departments of every railroad in the Dominion and still have over a million dollars left as waste.

Loss and Robbery

The largest single item is loss of entire packages. Add to this robbery and you have about 20% of the total claim payments. In nearly every case a lost package is nothing more than a lost record. If the record shows what happened to the box the package is not lost. So, to find lost packages, find where the record stopped.

The largest item is unlocated damage. This is a damage not explained by investigation. Freight going into car in good condition and coming out at destination damaged, specific cause unknown, but influenced by the following: strength of package or crate, method of stowing in car, weight of load in car, mechanical condition of car, position; length of time car en route, the degree of handling car receives in the train and in the yards.

This subject can probably be hooked up with rough handling of cars, which is the next largest item. We know from what we see out in the field that a large portion of our damage is due to the quality of the handling the car receives. Opinions differ on what constitutes rough handling.

We find that freight train car repairs stand at $29,938,025. This is 8% of the total operating expenses. It is certain that claim prevention will have an important bearing upon reducing this item, and every operating, transportation and mechanical man is interested in making that reduction. At the last annual meeting of the Freight Claim Division, Mr. J.A. Pilcher,mechanical engineer of the Norfolk & Western, delivered a talk on this subject, the burden of which was, that cars equipped with spring draft gears must not be brought together at a speed greater than two miles per hour at time of impact. He chose spring draft gears on the theory that we must bring the force of our handling down to meet the strength of the weakest link and then he suggested we cannot continually make heavier cars to meet heavier handling, and that men must learn to ease up and not hit cars just because they look like they will stand it—repeated drops of water will wear away granite.

To answer a thought which may arise in the minds of some, I want to draw a distinction between switching at two miles per hour and coupling at two miles per hour—two different things. If an engine foreman can switch fast and not damage the scenery, he is a good man. If he can so line up the work that every member of the crew understands what the other fellow is trying to do, and between them they have their speed down to two miles per hour when the cars come together, he is a good prevention man. It is worth study in every yard as shown in the claim accounts and the car repair bill.

Unfit Equipment

The next largest item is defective or unfit equipment to which we can add wrecks. Over 50% of any activity directed to any of the four items just mentioned will influence for good each of the remaining three items. You can readily see why it is so—all of them together account for about 40% of the total claim expenditures. With this we can keep in mind that maintenance of equipment, taking 23% of the total op- [illegible] ind reduction in proportion to the effort devoted to reducing transportation account insofar as relates to unlocated damage, rough handling, defective equipment and wrecks, or derailments as the operating man likes to call it.

Therefore, we have rough handling causing damage to freight, damage to equipment, which results in leaky roofs, sides, etc., impairs the running gear or

placement. What can we do about this? My first thought brings me back to the committee arrangement where the men can find occasion to discuss better methods: where one switchman can talk "turkey" to another switchman about his signalling methods and bring about a better understanding, and the art of giving a signal so the other fellow will understand it and not come down for three car lengths when he had but two to do; where a conductor can tell an engineer what happened on the rear end and not start to fight about it. You could not put one engineer in the cab to show something to the other fellow, but he could do it at meetings and get away with it and thus be of help to the travelling engineer, trainmaster or road foreman of engineers, if one is on the road.

Train and yard men can tell the car men about bad hand brakes, and the car men need not hesitate to tell the switchmen about pulling air hose with the engine and what that leads to. These meetings are the greatest kind of help to superintendents, trainmasters, yardmaster, or other staff officials in keeping abreast of things that create claims and enlisting the help of the rank and file in getting right things done in the right way, and at the right time.

Here are some of the things for discussion with the idea of using them with variations to suit the conditions in each yard:—Restrictions as to commodities that will be sent over humps. Restricting the number of cars that will be handled in one cut; some restrict to 15 cars, others 20.

Discussing signalling methods to avoid misunderstanding and to learn the best method for each particular yard. The man on the engine knows the num-

*Author is special representative of the Freight Claim Prevention American Railway Association, and presented this material before the members of the Canadian Railway Club at Montreal on January 10th, 1922.

ber and weight of cars, but he does not always know how far he is going. Shall the engineer take signals from the engine foreman only? What does a man going from one yard to another know about the interpretations applied to the terms used by switchmen? When it is used, is the wash-out signal a quick stop or a slow sign?

What is behind the failure of couplings to make? Plenty of room for discussion here. What is the best brake equipment for switch engines, straight air or automatic? To what extent are trains classified to reduce switching en route? Do enginemen know the effect of releasing brakes on long trains when running at low speed? Many frightful angles to the brake question and a wide field for discussion.

Trouble With Brakes

Brake pipe leakage causing trouble with air brakes—much of this results from pulling air hose apart with the engine. Every trainman ought to uncouple the hose and not simply allow the engine to pull the coupling apart. A live committee in any terminal will soon put a stop to that practice.

Stopping trains by applying air at the rear end, either by opening conductor valve, angle cock, or tail hose is another practice that would be discouraged.

How much time should be allowed for the inspection of train after being made up? Is enough time being allowed in any particular yard? It is said stretching trains entering or leaving terminals is a great help to car inspectors and enables them to test the air in the least possible length of time. The question of the proper place in trains for old and weak equipment is a live subject which should be kept in the minds of yard men at all times. Reporting bad brakes and hand brakes, and long brake chains, for proper corrective measures will help the rough handling account, also checking yard delays to reduce the extent of handling and opening merchandise cars for inspection of condition of load before or after lined up for road.

Yard air testing plants connected up with freight houses, team tracks, etc., where practicable, will be of help. With this goes the question of triple valve cleaning, oiling, ring adjusting, etc. Among the aids to supervision in this work can be mentioned:—

The flood lighting of yards, conductor's air-brake cord, report of draw-bar failures, report of knocked down drawheads, and report of yard damage. These to be followed up with a view of correcting the underlying causes.

Out on the road we have a wide field for educational work with train and engine men on such subjects as:—Negotiating grades, the control of slack action, uncoupling engine before making water tank stops, bunching slack and stopping trains before entering switches, the general subject of starting and stopping, the reporting of train line leaks, supplying suggestion cards for use of train men in reporting prevention matters.

The Instruction Car

Then there is the matter of getting the men to visit the air brake instruction car, where one is used. At stations we have the matter of methods of pulling and setting house and team tracks, especially where partly unloaded cars are involved and the problem of watching the traffic volume to provide as many set out cars as possible to reduce merchandise handling — the less handling, the less claims.

The above are a few things having a bearing on unlocated damage and rough handling, some of the matters which must be gone into, if we are to talk rough handling to the men in the field, because it is necessary to neutralize the excuses which are afforded to explain such failures, thus clearing the way for an intensive campaign among train and yard men.

A good plan, where it can be worked, is to choose certain engineers who are willing to place their minds on the subject, to study train handling; make a write-up of their observations and circulate this to employees. The same can be done with respect to other employees writing from their standpoint, such as conductors, yard foremen, car foremen, etc.

Claim prevention calls for education and co-operation. We must educate ourselves and the other fellow. There are conflicting opinions as to what constitutes education for the purpose of preventing claims, but we can call it education in good service—it is nothing more. What we do to prevent rough handling will, of course, reduce the number of derailments and reduce the money. After an accident does occur, the big thing is to salvage as much freight as possible. To this end, wreck outfits should be equipped with tarpaulins and cooperage supplies to take care of any situation, and as the car department usually looks after picking up wrecks, the wreck master should be a member of some committee, at least he should be kept posted on claim prevention matters, so he will be interested, and will never fail to open a car which is lying on its side, get his men inside and re-arrange the freight in such a manner as to cause the least damage when car is righted. He should know exactly what the car contains before taking hold of it with the big hook. It may burst open. If the freight inside the car is arranged for such a contingency, or shifted in position for the proper righting of a car, a lot of money can be saved.

Safety Department

The safety department of a railroad can consider freight claim prevention along with its safety work. I do not suggest that the work can be mixed, but simply want to show how they are interested because we, as railroad men, ought not to allow a bad practice or condition to go unnoticed, particularly when we can reinforce our argument from two standpoints.

Here are some examples:—

A defective running board or apron over which freight is trucked might go off under a truck; if so, personal injury is possible, plus damage to freight. Leaking tank cars cause loss of oil and danger of fire, explosion and personal injury. Dragging arch bars, or brake beams, can be talked from both standpoints; so can overloading of coal on tender or coal cars; so can holes in freight platforms. Also bad breaks and methods of signalling in yards. These are just a few to show the wide range of overlap in the work of men who may be looking after safety first as well as those who may have sole charge of doing things to prevent freight claims.

All work to eliminate rough handling in transit and defective equipment combines safety first with safety to freight. It will be observed that delay is another large item. The rule should be to keep freight moving—it is the slow drag that keeps moving that gets freight over the road. The remedy lies in terminals, a good daily yard check and a live prevention committee will solve the problem. Other causes such as hot boxes, resulting in set outs en route, is a matter of proper journal packing to be looked after by the car department.

A Large Item

In talking about delay, we must not overlook the dispatcher. Keep him posted on claim expenditures, particularly the truck dispatcher. He is the man who puts the stuff over the road. Another point to be considered is that anything which reduces delay will reduce per diem. Many disputed points on claims would be decided in favor of the freight claim agent, were it not for some delay along the route. Delay means increased hazards of all kinds. Any road with an agricultural department may get them interested in crop conditions and field diseases in connection with fruit and vegetable loss and damage. Big opportunities await the railroads in this field of possible prevention activity.

It will be observed that defective and unfit equipment is one of the large items. In presenting this problem to you, I can do no better than state it as it appears in a report the freight claim division has just drawn up for the consideration of the mechanical division, as follows:—

For seven months ending March 31, 1921, defective and unfit equipment account summed $5,876,056, or 9.9 per cent. of the total payments, divided as follows:

Car Load	$5,322,770
Less than Car Load	553,286
Total	$5,876,056

against total payments divided as follows:

Car Load	$32,573,286
Less than Car Load	26,996,110
Total	$59,569,396

It may interest readers to know the principal commodities represented by defective equipment payments:

	Car Load	Less Car Load
Grain	$1,765,462	$53,202
Coal and Coke	1,076,387	17,250
Flour and Mill Products	901,923	95,397
Sugar	394,652	33,170
Fresh Fruits and Vegetables	103,672	8,388
Cement, Lime, Sewer Pipe, etc.	74,985	8,456
Live Stock	56,228	1,220
	$4,373,363	$217,083
	217,083	
Grand Total	$4,590,446	

As a matter of information, we show the percentage of defective equipment payments charged to specific causes, as taken from figures compiled at different times by individual roads as a guide in determining the relative importance of the subjects detailed in what is to follow:—Defective equipment sums 9.9 per cent. of the total payments, or on basis of $10,464,000 per year at the present rate of payment of $5,876,056 in seven months. Wet through the door, will account for 5 per cent. and up to the above figures, depending upon the rainfall and the kind and nature of storm encountered, as such damage results from wind blown rain only. Leaky roofs will take care of 30 to 60 per cent., depending upon the territory and the weather. Nails and bolts will account for 4 to 6 per cent.

About 1 per cent. of the above payments can be charged to dirty floors. The average for six selected years on two roads was .859 per cent. In discussing defective equipment losses as applied to grain and coal, we must consider the item of "Unlocated Loss." This is a loss the specific cause of which was not determined by the investigation. This item is influenced by defective equipment.

The payments on grain for the seven months were as follows:

Defective Equipment	$1,765,462
Unlocated Loss	573,053
Total	$2,338,515

Under the method described above, this sum will roughly divide as follows: 25 to 35 per cent., scale discrepancies, 5 to 14 per cent., defective lining or siding, 5 to 6 per cent, defective grain and other doors. The percentage varies on different roads, depending upon the conditions.

In these days of double loading, it is difficult to accurately determine how much of our so-called rough handling, unlocated damage, and unfit equipment, damage to carload sacked goods, is due to the many obstructions now appearing on the inside of box cars, or how much might be saved by building cars with smooth interiors, such as is provided in refrigerator cars. The loss and damage on carload flour, mill products, sugar and cement, summing about $300,000 per month, gives an indication of the value to be derived from a study of the question as applying to these and other commodities—bulk grain, for example.

During the seven months $444,229 was paid account damage to live stock. The physical condition of stock cars has an important bearing on this item, particularly with reference to horses and mules. As a sidelight on horse and mule damage, it may be mentioned that bruised eyes result from striking obstructions in the roof, resulting from the habit such animals have of throwing up their heads.

Defective Equipment

One phase of defective equipment affecting claims concerns the transfer of bad order loads. One large road making a check for a 30-day period reports 500 such cars transferred at a labor cost of $11,000 in adidtion to the claim hazard. This cause, of course, is influenced by unfair handling, yard damage, etc. On the theory that the less handling freight receives, the less damage will occur, it is thought that car foremen could well give consideration to the matter of reducing this handling by an inspection to determine methods of running a car without transfer, taking into consideration:—The nature of the load, the condition of the load, the length of the haul to destination, and the possibility of temporary repairs.

On Prevention Day (May 18, 1921) during our 1921 annual session, the following action was taken in connection with consideration of the above subject:

"That report be made to the Mechanical Division of the A. R. A. that it is felt that losses due to defective equipment are of such extent as to merit consideration by that division with respect (1) to agitation for extensive repair of equipment; (2) need for drastic regulations as to selection of equipment for grain, flour, mill products and coal; and (3) enforcement of rule for stenciling of bad-order, leaky-roof cars." Every railroad man should be interested in making the railroad successful. He should do what he can to prevent waste of railroad revenue in satisfying loss and damage resulting from failures in transportation.

All of this expenditure is not preventable in the ordinary sense of the term, but the claim man, paying this money day after day, sees so much that he thinks and much which he knows can be prevented, that the freight claim division of the American Railway Association is placing this subject before those who we are sure will be able, from their own knowledge of what is right in this particular field, to reduce this waste after the claim man points out the causes with his idea of the remedy available.

I have touched upon methods of interesting the rank and file, but they cannot be expected to go any further in this work than their opportunities will permit. To produce this opportunity the supervising heads of all divisions of each general department of railroading must be interested. Previous remarks have taken care of the important features of the operating and mechanical departments. There are a few, additional, however, of equal importance, and I shall attempt to show how they are interested in this question and how they can help by encouraging their men to watch those features of their work, the wrong handling of which spells claims.

The car department can do much to prevent the use of cars unfit for the class of freight to be loaded. Equipment may be scarce, but a good system of carding cars, showing class of freight they are fit to carry, and a proper interest by yard men, will always produce the few good cars to be found in every yard to load the few high-grade commodities loaded from that place every day. In theory, when a merchandise house is set for the day, every car is one fit to carry merchandise. Any cars found unfit must be used as they stand set out, or fixed up. We know it doesn't pay to break up a house setting, so the tendency is to use the car. This car, if used, will be loaded to some freight house at some other place, perhaps a small place where the house foreman must make his own empties. In any event wherever it goes, it likely will be unloaded at a point where it at once becomes another merchandise car, and this may go on for weeks and months until finally the car gets out of the merchandise channel and is set for the loading of mill products or other commodities.

Puts Cars In Shape

The point here is that a car once in merchandise service is likely to remain in that particular channel for a long period of time carrying a new load each few days. If the condition of that car is such as to produce claims, it is of more than passing importance that it be put in shape before it starts out. The car department can do much to get this car in shape even if by use of temporary repairs. The car may show daylight. Temporary repairs to missing sheathing will save damage. Perhaps it will be possible to draw from doorposts protruding nails left for bracing previous loads. Perhaps they can replace bad hasps or locks, as a car in that condition is a standing invitation to be robbed each time it is loaded. This can be done on all cars which reach the rip trace for any purpose. Card leaky roofs so they will not be used for high-grade commodities.

The Purchase and Storage Department can help when buying new equipment by following the Mechanical Division's recommendation and help get money-saving devices into effect. They could have car builders cut off bolt ends where they protrude beyond the nut on inside of cars.

They can have their men represented on prevention committees so they can learn the many ways of co-operating

(Continued on page 42)

WHAT OUR READERS THINK AND DO

ANSWER TO QUESTIONS

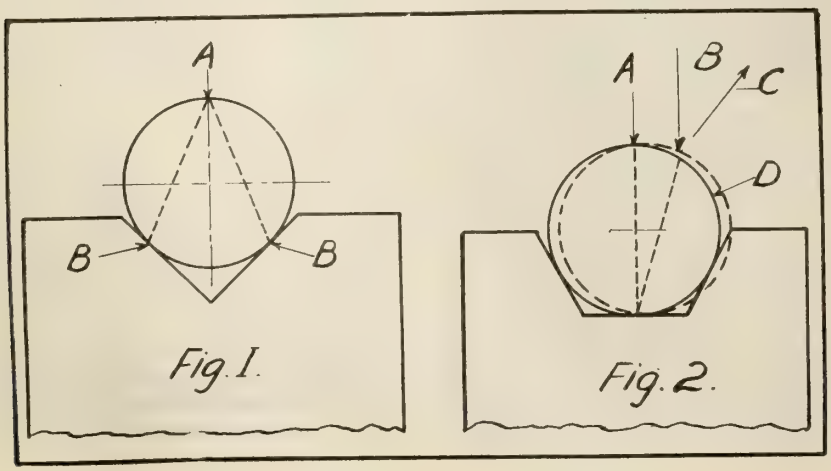
By I. N. BRIGHAM

Replying to "Can you answer these questions?" in the December 22nd issue of Canadian Machinery, I hope the following will help the questioner somewhat at least.

Regarding the query as to the variations in the reading on the Scleroscope on the different size balls. The enclosed sketch shows the right and wrong way to test balls. Fig. 1 shows the wrong way to support the ball as in a conical depression, while Fig. 2 is the right way to support small balls. "A" shows that the ball must be struck in the center, to avoid the side glance of the drop hammer, as at "B" and "C" and vibration at "D." If the balls are ground flat and parallel, and struck directly above the point of support, the reading will be correct. If your correspondent will read the Shore Scleroscope; its Application to the Arts, he will find out the reason he got so much variation in the readings. It is sent free on application. The writer used the Scope for testing gauges, cutting-tools, etc., during the War, and found it very reliable when properly applied.

Replying to query as to how threads are cut in scroll chuck jaws; this is done on a scroll lathe designed specially for cutting scrolls used for operating the jaws of scroll chucks.

The part to be operated on is held either in a chuck or special fixture attached to the spindle of the lathe. The scroll lathe built by the Automatic Machine Co., Bridgeport, Conn., has two tools held on slides, which, in turn, are mounted on a carriage. This carriage travels forward and backward along a bed located at right angle with the axis of the work-spindle. There are no idle movements because one tool is cutting while the other tool is returning. The tool-slides withdraw for the return movement, and, when the tool reaches the starting point, it is automatically fed in to a predetermined depth for the next successive cut. When the cut is finished and the tool, after being withdrawn, is on the return movement, the tool in the opposite slide is taking a cut. When the spiral groove has been cut to the required depth, the feeding of the tool is automatically discontinued. The travel of the carriage and the position of the bed relative to the work are adjustable. The lead of the spiral is varied by means of change-gears which impart motion to the lead screw, and either a right-or left-hand spiral may be cut. After the grooves in the jaws are cut, they are relieved for the travel of the jaw.



NOTHING NEW UNDER THE SUN

By WALTER ROWLANDS

Some time ago an article appeared in a mechanical journal under the heading "A new idea in upsetting," and went on to say that a very large automobile manufacturer had built and equipped at considerable expense an upsetting dept. to make gears and other parts off the bar, thereby eliminating considerable waste caused by drilling the holes. The idea was to upset the piece in one or more impressions in the dies, and then in another impression to punch the hole. The bar would then be separated from the piece required and when reheated would go through the same procedure again.

A few years previous to the above article appearing in print the writer had charge of an upsetting department in connection with a forge, and had occasion to get out as soon as possible a considerable quantity of hexagon nuts of large diameter, which were required to be rather more than standard size across the face. Fortunately I had an old pair of dies that suited the job, and after taking a light cut over the face I turned them over and put the impressions on the backs. The job cost very little money and in a very short time we were ready for the job of turning out hexagon nuts in exactly the same way as the supposed new idea.

By heading, and then punching the holes which released the bar, and by having several pieces in the furnace, the job of making the nuts was fairly fast. The same thing happened to the writer some years later in another firm where the purchasing agent had neglected to order some square nut blanks, (not threaded), and as the time was limited in which they would be required it was impossible to obtain them. Our nut machines were too small for the job so we made bolt heads and punched the bar out and the nut dropped in the floor. The strange thing about this job was that the purchasing agent omitted to order the blank nuts the following year although he was told the first time that making the size blank by this method was too slow and costly and was only done in the first instance to enable shipments to be made on schedule time.

NEW HAND TOOL

The breast drill is one of the most familiar of small hand tools in engineering shops, and a new tool in a novel form has been brought out by a British firm. This tool provides four separate speeds. The usual toothed crown wheel is replaced by a disc with four concentric circles of conical holes. On the drill spindle there is a pinion which meshes with one circle of these holes. In order to change the speed of the drill the pinion is moved from one circle of holes to another. At all speeds the gearing is said to run smoothly yet rigidly. The tool is also noted for its lightness.

DEVELOPMENTS IN SHOP EQUIPMENT

EXTERNAL AND INTERNAL LAPS

The R. & C. Lap Company, Davenport, Iowa, has recently placed on the market a line of standardized external and internal laps. These have been designed and developed with idea of producing a lap that can be used in production manufacturing in the shop, as heretofore lapping has been almost universally confined to the tool room. The laps can be used with excellent results by labor that has not had previous experience in lapping operations. All laps are provided with interchangeable shells which are, of course, replaceable. Two grades of shells are provided, the use of which depends upon the speed of cutting desired and the type of work. These laps are made in sizes from one quarter inch up. The laps consist of a floating type shank, and an expanding device for adjusting the size, and also to take up wear of the soft metal shell which is charged with abrasive. This adjustment precludes any chance of a lap sticking in internal lapping operations, and always allows the lap to be removed from a piece of work when lapping is completed.

Although the lap can be contracted in the work after the operation is completed, it cannot be made to expand beyond the original micrometer setting, which maximum diameter limit is secured by a lock nut adjustment of the expanding mechanism. It is claimed that the expanding mechanism is so constructed that a constant diameter is maintained from end to end of the lap, which fact, of course, produces work of constant diameter. The laps are fitted with standard shanks and may be used in a lathe, drill press, or by hand. The lap may be expanded to the proper size by means of the adjusting nut, and this setting may be maintained by means of a locknut. The abrasive is then applied, and the work is lapped in the usual way.

REAMING AND CHAMFERING MACHINE

The Murchey Machine & Tool Co., Detroit, Mich., has recently developed and placed on the market, a machine which is intended for reaming and chamfering pipe nipples and other pipe fittings. The pipe nipple, or whatever piece of work is to be machined, is held in a central vise which is opened by pressure on a foot treadle and is closed automatically when the pressure of the foot is released. There are two spindles which carry the tools. These spindles are mounted on opposite ends of the machine, thus both ends of a piece of work are machined simultaneously. Both these spindles are operated through one capstan wheel placed at the right hand end of the machine.

When a nipple has been reamed and chamfered it is knocked out by the insertion of the next nipple and drops into a receptacle which is regularly provided as an integral part of the machine. The jaws of the vise are hardened and ground. Wide bearings are provided for the slide on which the vise operates. Provision is made so that the work in the vise centers itself as the tools start cutting. A countershaft is provided on which are two drive pulleys of different diameters which give two independent ranges of speed to the machine.

In addition to this a four-step cone pulley is provided. The capacity of the machine is for nipples from ½ to 2 inch pipe and lengths up to 12 inches can be accommodated. The machine under test recently produced six hundred and fifty ¾ in. nipples per hour and another test showed that the machine was capable of machining three hundred and seventy 1½ in. nipples per hour. The approximate weight is 1,200 lbs. and the floor space required is 8 x 2 ft. An oil lamp is included in the regular equipment which furnishes cutting lubricants to the tools. Although primarily designed for reaming and chamfering the machine can be equipped with dies for threading but in this case the capacity is for fittings from ⅛ in. pipe to ¾ in. pipe sides. Tees, valves, studs and other work that requires threading on both ends can be easily taken care of in this machine.

RENEWABLE PLUG GAUGES

Several sets of plug gauges, on which the gauging ends are renewable, have been placed on the market in wooden cases by the Coats Machine Tool Co., Inc., New York. The design is intended to make replacements possible with a minimum of cost. The gauges are made of hardened steel and are ground within an accuracy of 0.0001 of an inch.

There are two principal sets of gauges supplied in cases. Set No. 1 comprises fourteen sizes from ¼ inch to 1¼ inches in diameter, the sizes increasing by 1/16 of an inch, up to 1 inch, and by ⅛ inch from 1 inch to 1¼ inches. The four smaller sizes are made solid with the handle. Set No. 2 includes sizes from 1⅜ inches to 2¼ inches in diameter increasing by increments of ⅛ of an inch. In addition to these standards, renewable limit plug gauges are also manufactured and supplied by the same concern from stock. Each gauge of the limit type, consists essentially of three parts, a "Go" end, a "No Go" end, and a handle. The handles are interchangeable and one size will fit a range of plug sizes. Both English and metric measurements are carried.

QUICK-CHANGE DRILL CHUCK

The "Save-All" Tool Co., Waltham, Mass., has recently placed on the market a positive, safety, quick-change, chuck for drills or other tools with taper shanks. The tool is held in a collet which may be slipped into the chuck when the sleeve on the latter is raised. When the sleeve is lowered jaws engage the taper end of the collet and hold it in place. A safety device, in the form of a pin that shears, prevents the breaking or burning of tools. The pin is held in place by a pointed screw which seats in a groove in the pin. After a pin has been sheared it is readily removed by loosening the screw.

It is claimed that the construction of the collet is such that members do not stick when tools are changed. A special feature is a compensating collet lock which automatically takes up wear and eliminates end motion while a Bristol set screw prevents the tool from pulling out. Tools can be changed while the chuck is revolving. Release is obtained by tapping an ejector on the small end of the collet. One of the standard chucks accommodates drills having Nos. 1, 2, 3 and 4 Morse type shanks. Other types accommodate an equally wide range. All parts are hardened except the shearing pin.

THREAD-LEAD GAUGE

The Toledo Tap and Die Co., Toledo, Ohio, have placed on the market a Thread-Lead Gauge, which is designed to quickly and accurately check the lead of all taps and accurately threaded studs. The gauge has an arm 8 inches long that is pivoted on adjustable angle bearings and carries at its outer end a hardened and ground conical point.

The arm also has a hardened button which comes in contact with the plunger of a dial gauge, on which is positively registered any variations between a master thread gauge and the work being inspected. A second hardened and ground conical point is mounted on a slide which may be operated horizontally, so as to vary the distance between this point and the pivoted arm. The distance between these two points can be varied from ½ to 2 inches.

In using the device the master thread gauge is first placed in the proper position and the instrument adjusted to it. Then the dial gauge is set at zero, and after removing the master gauge, the specimen to be inspected is inserted in the machine and any variation in lead, from that of the master thread gauge, is read directly from the dial gauge.

The dial may be furnished to read either in thousandths or ten thousandths of an inch. The arm and pivot points are fully enclosed so that they are not accessible to curious operators who may wish to tamper with, and adjust them. For the same reason they are practically free from harm due to abuse of the instrument.

ELEVATING TRUCK

The Western Tool and Manufacturing Co., Springfield, Ohio, has placed on the market an elevating truck. The construction is entirely of iron and steel, many of the parts being hand forged. Two front wheels, placed only a few inches apart, swivel on thrust ball bearings. The whole four wheels are provided with cage roller bearings. The truck has a lift of 1½ inches, and it is capable of handling weights up to one ton through the efforts of one man. The turning radius of truck is its own length. The dimensions over-all are, length 46 inches, width 26 inches. The standard platform dimensions, with the over-all dimensions given above, are, length 38 inches, width 23 inches. However, special platforms of greater length can be provided on special order.

CLEANING MACHINERY

A cleaning machine designed for cleaning small parts such as roller bearings, gears, ball bearings, drills, milling cutters, motor and generator parts and other small tools has recently been placed on the market by the Black & Decker Mfg. Co., Baltimore, Md. The machine consists of a cast iron pedestal, at the top of which, a bowl is mounted. The bowl is 13 inches in diameter and 12 inches deep. It has a fine mesh brass screen supported about 5 inches from the bottom. The housing of a plunger pump is cast integral with the bowl. The bowl has a safety cover so arranged that it cannot be left open. The cover is lifted by means of a convenient handle that operates the pump.

A gallon of kerosene, gasoline, or any other desirable cleaning liquid is poured into the bowl, and the operation of the pump forces a stream of this fluid toward the center of bowl from the side. The parts to be cleaned are held under the stream so that all dirt and chips are washed away and deposited on the screen below. The fluid passes through the screen and on to the pump to be used again.

PORTABLE WELDING OUTFIT

There has recently been placed on the market a welding outfit that is contained in a fibre case to facilitate the transporting to a job. This outfit has been brought out by the Davis-Bournonville Co., Jersey City, N. J. The various units in the case include: a torch, three extension tubes, five welding tips, decarbonizing tube, oxygen regulator, twelve feet of oxygen hose and connections, twelve feet of acetylene hose and connections, spark lighter, pair of colored glasses, and torch and regulator wrenches. The copper extension tubes can be furnished in any length desired. The tubes are flexible thus making welding possible in inaccessible places. It is claimed that the outfit is suitable for any welding job.

QUICK CHANGE DRILL CHUCK

The Collis Company, Clinton, Iowa, has designed a quick-change drill chuck. It can be used in the spindles of lathes, drilling machines, screw machines and other types of machines including those having rapidly revolving spindles. The chuck can be operated by one hand and collets inserted or released when it is revolving at speeds up to 1,500 revolutions per minute. The ease with which a tool can be replaced adapts the chuck for use where several operations are performed on one spindle without removing the work.

The collets have taper shanks and may be used in either a vertical or horizontal position. Different collets can be used to accommodate the various tapers or straight shanks of drills and taps. A special type known as the "Use-Em-Up" enables drills with twisted or broken shanks to be used. In such cases it is only necessary to grind a flat on the remaining portion of the shank. The chuck is manufactured in six sizes.

PORTABLE ELECTRIC DRILL

The United States Electric Tool Co., Cincinnati, Ohio, has developed a small portable electric drill having a capacity for drilling holes up to 5/16 inch diameter in metal. The drill has an aluminum alloy housing, weighs about 5½ pounds, and has an over-all length of 9 inches. Hardened chrome nickel steel gears, running in grease, are provided. The electric switch is located in the handle so as to be conveniently controlled by the thumb at all times. The motor is of the universal type, air cooled, and operates on 110 or 220 volt circuits. When used on alternating current circuits it can take care of current from 25 to 60 cycles single phase. It is capable of being used on direct current if the voltage is correct. Connection is made to any lamp socket. The drill is particularly suitable to corner drilling

VERTICAL BROACHING PRESS

The Lucas Machine Tool Co., Cleveland, Ohio, have recently placed on the market a vertical broaching press the ram of which is driven from a train of gears having as a prime mover an electric motor. The application of the machine is for the operation of push-broaches, requiring only short broaches, allowing the work to rest in the horizontal position, permitting of easy lubrication, and providing a convenient means of operation for the workman. The drive between the motor and the gear train is through the medium of a leather belt. The motion of the train is controlled by a friction clutch in this pulley which engages a wormwheel. The length of the stroke can be regulated automatically by a dog which can be set at any desired point and will reverse the motion of the ram. A gauge is mounted on the ram, so as to register the pressure that is exerted.

The machine is built in two sizes, the smaller requiring a 7½ horse power motor, the larger a 10 horse power size. A pump supplying cutting lubricant can be included, although this is not part of the regular equipment. The large machine exerts a pressure of 30 tons and the smaller a pressure of 15 tons. The speed of the ram on the large size is 9 ft. per minute and on the small machine is 6 ft. per minute, while the return speeds are 21 and 15 ft. per minute respectively. The maximum distance from the base to the ram in its top position is 48 inches for both sizes, although a high-pattern type of machine can be furnished to special order with a height of 60 or 72 inches. The distance between the housings is 25 inches for the small machine, and 30¼ for the large. The speed of the driving pulley for both machines is 500 r.p.m. The net weights are 2,900 lbs. and 3,800 lbs. respectively.

MOTOR DRIVEN ROAD ROLLER

The use of steam for driving road rollers has been the universal practice for so long that the change to the internal combustion engine strikes one with a peculiar degree of surprise. At a recent transport exhibition in London, a British firm showed a type of motor road roller weighing eight tons. It is a three wheel machine driven by a 20 horse power engine running at 1,000 revolutions per minute. Petrol is used for starting, and afterwards the engine runs on crude oil. A single lever effects all speed changes, giving three speeds—two and a half, one, and one half miles per hour—forward or backward. Ample power is afforded for hill climbing as the engine runs at full speed when the roller is going at its lowest speed.

There Is Profit In It—If

ON ANOTHER page of this issue appears an article on "Repair Work and How It Can Be Made Profitable." Everyone should make it a point to read this article for it contains many hints of value. Some people imagine that a repair shop is a glorified wood shed into which has been placed some old-fashioned, second-hand machinery. The proprietor is sometimes pictured as an overalled member of the gang, dirty in appearance, and a rapid tobacco chewer, but why go further with this very much misunderstood personality.

The modern repair shop is just as carefully housed and laid out as any manufacturing plant. True, there still exists the type of small shop which is content to putter away in some back alley, but these places are not to be classed as genuine repair concerns. You might as well compare an up-to-date garage with the little shed out in the country that has a whitewash sign proclaiming the fact that ANY make of car can be repaired there while you wait.

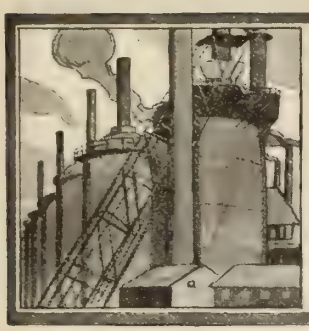
The size of repair shops differ. The style of plant may vary, but look inside. The equipment and general appearance tell the story. One can readily tell whether high-grade work can be expected or not. While many mechanics can turn out a better job on a fairly good machine, than others can on the best tool available, still we cannot dismiss the necessity of first-class equipment on these grounds. All the more reason why the capable worker should be given the best machine possible.

Another point of importance, and one which unfortunately does not receive the attention it deserves, is that of keeping track of costs. Many repair shop owners are content to give a price on a job which they believe to be high enough, secure the order, then think they have made money, when in reality they haven't. Usually, it takes a few years before this type of man finds he cannot pay his bills, and we soon see a sign "For Rent" on his premises.

There is good profit in the repair business IF certain factors are continually kept in mind. The business should be handled in a regular, and not in a haphazard manner. A proper, but simple, cost system should be adopted, overstocking of material should be carefully avoided, and only the best type of mechanic should be employed. There is an erroneous impression existent that any old mechanic is good enough for the repair business. This viewpoint is ridiculous, for the better the workman the quicker he will complete the repair, and the greater the profit to the owner. Last, but perhaps most important of all. The foreman, or owner, as the case may be, should see that he is always dressed in such a manner that he will create a spirit of confidence in the minds of his customers. He should be able to leave the shop in charge of some competent employee, and devote his activities to the securing of orders and otherwise building up the business. Many an order has been lost, because owners, or foremen, of repair shops, have been too busy (?) to give proper attention to prospective purchasers.

A Year For Energetic Men

READERS of Canadian Machinery may approach the present New Year in either of two moods. They can feel dispirited, pessimistic, hesitant, finding many arguments to support their attitude, or they can resolve to encourage optimism, enterprise, and more business. Each individual exercises an influence on those around him. That influence may be buoyant or heavy. A community is a collection of individuals and what communities think and do becomes public opinion. Public opinion is one of the greatest of human forces.



The most casual observer knows, of course, that there has been a period of depression. That it would come, as certain as evening follows day, was anticipated by all who took the trouble to read lessons from the past. History repeats itself with faithfulness. During every war of magnitude there has been a period of lavish expenditure, inflated prices. Always it has been followed by a cycle of contraction and readjustment. The pendulum of time has always swung in one direction as certainly as it swung in the other.

For a couple of years Canada, in common with other post-belligerent countries, has been balancing the two sides of its ledger. It has been taking stock, counting its elusive dollars against heavy obligations, clearing over-loaded shelves and settling back to sound economic principles of production and marketing. Every one has recognized that it is necessary to go through the valley before you can begin to ascend the hill on the other side. The question which thoughtful men, who have responsibilities on their shoulders, are now asking, is, whether the corner of the road has been turned?

Without suggesting that caution and shrewdness should not still be boon companions in every person's office or shop, at the same time no one who thinks it worth while to carry on business should forget that 1922 will see a considerable volume of business done. The world does not stop moving. It doesn't even sit down by the roadside to rest, but jogs along, pulling and complaining, laughing and grumbling much as it has done for centuries.

The note that Canadian Machinery wants to pass on is that a bright day is always more inspiring, more prosperous, than a dull, gloomy one. The business man who sees nothing but clouds around him will scarcely expect his colleagues, his staff, his salesmen or his business creators to look through brighter glasses. On the other hand, the man who makes up his mind to do things, generally finds a way to do them and the initiative hustle, aggressiveness of one person unconsciously radiates to others. 1922 may not be made a big year, but the story it will have written across it will be the story of busy, enterprising men. Dollards and pessimists rarely write anything.

Alberta coal is estimated to form 15 per cent. of the world's supply.

MARKET DEVELOPMENTS

Business Conditions Show Decided Improvement

Figures From Steel Mills Encouraging and Prices on Various Products Remain Firm—Channels of Demand Are Discussed—Ice Breaker Controversy Continues—Small Tool Market Improves.

THERE IS AN optimistic note in the various market reports this week which augurs well for future business. Although very early in the new year, various lines show considerable improvement already. The steel trade is holding up remarkably well, and prices remain firm. One concern reports an increase in business of 136 per cent. since our last market summary. This same firm also expects the present week to be still better.

Other dealers in steel goods report an even better volume of business than was expected this month. Several good orders have been closed and dealers are well satisfied.

The small tool market is picking up. Several concerns are replenishing their stock of drills, reamers, etc., and from now on dealers in this line expect a gradual improvement.

The scrap metal market has improved slightly and things are expected to be still better as time goes on. Machine tools are not very active, although enquiries are coming in all the time. When this business breaks, it will be in good volume.

The controversy in Montreal regarding the purchase of an ice breaker for the Government continues. No decision has been arrived at, the counter proposal being to buy a second-hand vessel.

American mills expect to keep the January rate of production up to the October-November, 1921, figure, and from present outlook they will be successful.

Furnace coke has stiffened in the spot market and weakened in the contract market. Recently this commodity could be quoted down to $2.75, but now $3.00 is about the average price. Contract coke has dropped from $3.50 and $3.25 to $3.10 so that both spot and furnace are now close together.

STEADINESS IN STEEL PRICES CONTINUES—CHANNELS OF DEMAND

PITTSBURGH, January 17th.—The point as to how much slowing down there was in steel demand and production towards the close of the old year is now settled by the appearance of the monthly report of the American Iron and Steel Institute for December. While the report gives the production only of 30 steel companies, there is information whereby the report can be interpreted, and an estimate made for the industry as a whole. The rate of steel ingot production in October was 23,000,000 gross tons a year, against scarcely over 10,000,000 tons at the middle of July, the low point, and a rate of 42,000,000 tons in the first nine months of 1920, when there was heavy pressure for deiveries, but when output was at only 80 per cent. of capacity because there were physical restrictions, particularly an insufficiency of train transportation accommodations.

In November the rate was about the same, a trifle over 23,000,000 tons. Now it turns out that the average rate in December was about 20,000,000 tons. Probably the rate was about 22,000,000 tons December 1st, tapering off sharply in the last week or two to about 19,000,000 tons, possibly a trifle less.

Average for Industry

An interesting point in connection with mill operations in December is that the Steel Corporation operated to much better advantage than the independents, doing about 48 per cent. of capacity, while the independents did about 30 per cent. This made an average for the whole industry of between 37 and 38 per cent. Frequently, and particularly in 1921, the corporation has had this advantage, not because it undersells the independents, since usually it is the other way, but because they get the preference from many buyers on account of the steadiness of its prices and the regularity of its deliveries. In the high pressure period of 1920, when independents were securing much higher prices than the corporation, the percentage rates of operation were practically even.

The slowing down in production towards January 1st does not indicate any change in fundamental conditions of trade affecting the demand for steel, being simply a reflection of the time of year. Frequently the mills are sold up so well ahead that the natural decrease in demand in the winter, and the withholding of orders just prior to the inventory period, does not materially affect the production, but this time there was a condition of buyers having been ordering from hand to mouth, makin a sensitive condition whereby the rate of production reflected the time of year

It is to be expected, therefore, that production will increase, and a rate of say 23,000,000 tons, the October-November rate, be attained again by the end of January. To the regular requirements of the trade that harmonize with present industrial and financial conditions generally there may easily be added an extra demand through buyers replenishing their stocks, which are far below normal. They are unlikely to restore stocks to what they have hitherto considered normal, but they are likely, now that steel prices are quite steady, to restore them to say 50 or 70 per cent. of normal.

Steel Prices Steady

The steadiness in steel prices noted recently becomes more impressive as time passes. Since the reduction of the American Steel & Wire Company on December 21st, caused by independents having shaded the prices previously held by the leading interest there has been no appreciable change in the general market price of any important steel commodity. Thus, there is steadiness in point of time, and there is also steadiness in point of tonnage, for nowadays large and small orders go at almost the same prices. Last August there was a big difference in some commodities between carloads of 2,500 or 10,000 tons.

The market remains quotable as follows: Bars, shapes and plates 1.50c; hoops, bands and hot rolled strip, 2.00c; standard steel pipe, 71 per cent. basing

discount; plain wire, 2.25c; galvanized wire, 2.75c; wire nails, $2.50; cement coated nails, $2.00 to $2.10; blue annealed sheets, 2.25c; black sheets, 3.00c; galvanized sheets, 4.00c; tin plate, $4.75. Blue annealed sheets are properly quotable at 2.25c, base. This applies to the lighter gauges. The heavier gauges do not sell now in blue annealed to any extent as plate mills are glad to take such business now, and sell on a plate mill basis, which makes a considerably lower basis than the jobbing mills would sell at. While hot rolled strips are quotable generally at 2.00c the same as hoops, the strip mills will shade the price much more readily than the hoop mills.

Channel of Demand

There is such a widespread popular misapprehension about the quantity of steel used by the automobile trade that it may be well to set down some facts. Leonard P. Ayres, who is an authority on this subject, forecasts the 1922 production of passenger vehicles at 1,100,000 Ford, and 700,000 all other types, representing a considerable increase over 1921 production. The production of trucks in 1921 is stated by another authority to have been 145,000. A fair estimate is that in such production about 700,000 gross tons of steel is involved. Those who think of the automobile industry using large quantities of steel probably overlook the oil industry, which has been using about 1,000,000 gross tons a year of steel tubular goods alone, besides steel of other descriptions, as in tanks, for instance. The actual steel consumption of the automobile industry can be given another interesting comparison, for the apparently insignificant commodity tin plate is likely to show a production in 1922 of 1,500,000 gross tons, i.e., twice as much steel tonnage in tin plate as in passenger automobiles and trucks. Another overrated consumer is the railroads. Rail orders for 1922 are now estimated to total 500,000 tons.

Pig Iron and Coke

W. P. Snyder & Company have sold 1,500 tons of Bessemer pig iron to an Ohio manufacturer at $19.50, valley furnace. For several weeks previous the market had been quotable nominal at $20, valley. Basic remains quotable at $18.25, valley, and foundry at $19.50. There was a fair movement in foundry iron in December in small lots for January shipment, while thus far this month the market has naturally been quiet.

Any amount of figuring can be done on pig iron costs and selling prices without any plain conclusion being reached. Selling prices in general are below the recent or present cost of production, and the really important question is whether they are below the prospective cost since the furnaces must perforce recognize what is coming. Thus, the furnaces still have large quantities of Lake Superior iron ore brought down in 1920, while prices for the 1921 season were reduced $1 a ton, and for the 1922 season they will be down 50c to $1 more, depending on how freight rates come out, both the rail rates from mine to lake water and the vessel rate down the lakes, since prices are named at Lake Erie docks.

Connellsville furnace coke has stiffened in the spot market and weakened in the contract market. Recently furnace coke could be quoted down to $2.75, there being odd lots pressing for sale. There seems to have been quite a clean-up, and one could hardly buy a lot of ten car-loads now at less than $3.00. On the other hand, first quarter contracts were made early in December at as high as $3.40 or $3.50, and late December at $3.25, while the latest contract now reported is at $3.10. Spot and contract are close together now, as they should be.

POINTS IN WEEK'S MARKETING NOTES

The Toronto market shows considerable improvement. The steel market is stronger, the small tool business has improved, and while machine tools are not selling rapidly, enquiries are coming in nicely. One steel concern showed a 136 per cent. increase in business during the past week, and expects to do even better this week.

The figures showing steel production for the closing months of 1921 are now out, and show a tapering off in December. This slowing down in production does not show any change in fundamental conditions of the trade, being simply a reflection of the time of year. It is expected that the October-November rate will be attained again by the end of January.

Steel prices remain firm, and several important commodities are listed in this week's Pittsburgh letter. Several comparisons showing the quantity of steel used by the various trades are given. The oil industry shows some remarkable figures, having used about 1,000,000 gross tons of steel tubular goods alone during the past year. The railroads are overrated consumers; they do not use up as much steel as some imagine.

Montreal reports an improvement in business this week. Although only slight, it is considered the start of still better things, as buyers' stocks are known to be very low.

Whether a new ice breaker will be ordered or an old one purchased by the new government remains an open question. Particulars of this controversy are given in the Montreal letter.

The Canadian Pacific Railway have brought down their annual budget and the claims of Western Canada will come first.

LOCAL CONDITIONS ARE MUCH IMPROVED

TORONTO, January 18th:—As far as the local market is concerned, the new year has ushered in quite a bit of improvement. Take for example the steel trade. January is never looked upon as a good business month for steel men, but here is how one dealer sums up the present situation.

"In the first week we sold a fair amount, but the following seven days we showed an increase of 136 per cent. So far, we feel we are going to pass the figures of last week, as orders are coming in nicely. The automotive industry is largely responsible for the influx of orders."

Another dealer in steel reports a good volume of business for this time of the year. Buyers are still placing their orders carefully, but as this merchant says, "I would much prefer to see orders coming to us in such a manner, than without sign of care or reasoning. It denotes a healthy atmosphere and shows that buyers have got both feet on the ground so to speak." The time when men ordered ridiculous amounts of steel is gone. The wise man to-day orders what he requires, not too short, but just sufficient. When he does so, both he and the dealer are satisfied.

To attempt to place your finger on a feature in the steel market is futile. Demand is general, with an occasional surprise. For example, quite unexpectedly, a dealer received a good sized order for stair treads this week. True, he had been working on this business for about a year, but it broke when least expected. However, he has the order, and seasonal or not, he is mighty glad to mark it down on the right side of the ledger.

We have been preaching for some time past that business can be secured, if one goes after it hard enough. A steel dealer voiced our belief word for word this week, when he remarked that he was searching every cranny in search of business. The result is that his firm is experiencing remarkably good business.

Small Tools and Supplies

The small tool dealer is in very good spirits this week, for business has improved considerably during the last seven days. Drills seem to be the feature, and as we predicted last week, these orders are the result of what inventory sheets throughout the country showed at the end of the year.

"The supply business is a funny one, and in it you meet many funny people," remarked one dealer to Canadian Machinery. "This is especially true of the automotive line," he continued, "and worst of all is the salesman trying to sell you some brand new specialty. He starts out by speaking about MY company, and from then on you hear nothing except the personal pronoun throughout his voluminous talk on WHY we should buy HIS product."

"Apart from the types we meet, the supply game is a funny one in other ways. Without notice, we will have a squint on some particular line. For instance, last week it was grinding wheels. We sold more of these wheels than was ever expected, and now this week we find plumbers' tools and supplies are in demand. Two or three weeks ago chain blocks were in the spot light, and so it goes.

"For the past week or two we have been receiving regular floods of literature pointing out the fact that NOW is the time to buy. There is no question but what it may help business, but that remains to be seen. Taking the supply business as a whole, we have no reason to complain," concluded our informant.

The Machine Tool Market

Things are still very quiet in this line. Evidently manufacturers are playing a waiting game, and refuse to buy until they absolutely need to. A few enquiries are coming in, but whether these will develop into orders depends upon the aggressiveness of the dealers themselves. They now have to convince manufacturers beyond a doubt that they require their particular tool. Competition is keen and is likely to remain so for some time to come.

The Scrap Market

A slight improvement is making itself felt in the scrap metal market. This is so slight however, that no importance is attached to it except that it is perhaps a start of much better things. The chief point of interest in all markets this week is the optimistic note prevailing. Everybody feels the turn has been definitely reached, and while hard plugging will be necessary for some, those in touch with the situation feel assured better business is not far away.

BUSINESS SHOWS IMPROVEMENT ICE BREAKER CONTROVERSY STILL ON

MONTREAL, Jan. 17th:—The volume of business passing during the last week has been a slight improvement over that of the past two weeks. However conditions are far from being satisfactory. Many things have occurred during the past week that would tend to cause matters to improve in the near future. At the same time the final figures for 1921 show in spite of all the talk of depression, the amount of business closed was such that it compared very favorably with the years immediately preceding the war. Yet behind all the reports of quiet conditions, there exists unquestionably a more optimistic spirt. In the Pittsburgh district reports show that the mills are operating at a better rate than was expected.

In Canada, buyer's stocks are low and purchasing is expected to be a little more active. American mills confidently look forward to being able to operate at about 70 per cent. capacity in the near future. The American Steel and Wire Company as noted last week reduced the price on cold rolled strip steel from $3.75 to $3.50, which shows a slight weakness still exists in some lines of steel business, and this tendency will no doubt be reflected to a certain extent in Canada. Connellsville coke is a little softer owing to the very poor demand existing since the middle of December.

The opinion expressed by Sir James McKechnie of Edinburgh, Scotland, a director of Vickers' Ltd., England, and of Canadian Vickers', is that "the Washington Conference is arresting the recovery of business, staying normal activities and developments, and until the industrial world knows just what is going to be done, whether fleets will be scrapped and ships destroyed, or a go-ahead building program decided upon, there will not be much progress made in restoring stability." These sentiments were voiced by Sir James while staying in Montreal this past week.

At a recent meeting of the board of directors of the British Empire Steel Corporation, the vice-president D. H. McDougall, said that "the corporation was facing the process of deflation in wages and until this was acomplished activities in both the steel and coal divisions, would not be very brisk. Until wages were reduced," he continued, "it was considered impossible to regain the St. Lawrence market for coal, or to compete with European and American prices in steel. The rolling of steel rails at the company's plants supplied a fair amount of employment at the present time, and coal is being mined for current requirements."

There still remains a certain amount of unemployment in the coal fields at Sydney, in spite of Mr. McDougall's statements, and it is sufficiently acute to warrant a special session of the Nova Scotia Legislature to deal with the situation in the Sydney and Cape Breton coal fields. It is feared that grave danger of trouble exists unless something is done, as some sections are destitute.

The Ice Breaker

The cancellation of the contract for the ice breaker which the late Meighen Government placed with Canadian Vickers's Ltd., has aroused a great deal of interest, and in some quarters, a storm of protest. No authentic report of what the outcome will be, is available at the moment. Official deputations from the company, and official representatives of the workmen interested, have visited Ottawa and have kept in communication with that city for several days. Diversified reports have been received. It appears that the ice breaker, "John D. Hazen," originally constructed by the Vickers' Co., in 1914 for the St. Lawrence work, can be repurchased for a sum in the neighborhood of a half million dollars. The present government have decided to investigate the offer with the idea in view of ascertaining which would be the cheaper, to build a new ice breaker, or to purchase the old one and repair it.

After these statements were issued in a more or less official manner from an apparently reliable source, a report comes from representatives of the late Meighen Government, that they had investigated the offer to purchase the old ice breaker and had concluded that it would be better business to build a new one, particularly in view of the unemployment existing in Canada at present. The report further states that the "John D. Hazen" has been sunk twice and has been subjected to very severe usage, that could be better termed as abuse. Bad as this seems to be, as it represents an unknown repair bill which might offset the original advantage gained by the low purchase price, the steamer is at present at Cherbourg, France, and the French government claim to own the boat. As the Russian Soviet government also claim to own the boat complications from the quarter are bound to arise. Thus, the saving that might be made is of a very uncertain amount. It is claimed by some that contract to build will be re-awarded to the Vickers' concern after a few minor changes in design have been made. Other reports have it that purchase of the old ice breaker will be made, and with the saving (?) effected several patrol boats will be built and employment given in that way. As it is, the whole affair is very uncertain, and no one can say at the moment with any degree of authority just what will be done. As it stands the contract is only held up, not finally cancelled. The purchase of the old ice breaker, on the other hand, is not an accomplished fact.

West Comes First

On the 12th inst. the Canadian Pacific Railway brought down their annual budget. This called for appropriations of 25 million dollars, but it was thought that when accepted this amount would be reduced to about 20 millions. The money is to be spent in road extensions and improvements. The claims of Western Canada are to be taken up first, and the Eastern demands will be dealt with later. It is a foregone conclusion that there will be little or no line extension in Eastern territory. As far as local construction is concerned, it has again been decided that work on the proposed line from Place Viger to l'Epiphanie which was started in 1912 and abandoned temporarily, will again be held over.

The original difficulty was with the then independent city of Maisonneuve, which would not come to satisfactory arrangements regarding street crossings. The line was to have cost several millions and would have materially reduced the distance between Place Viger station and Longue Pointe, providing a more economical coal route, as well

as speedier general service. The company is keeping the viaducts in shape for the eventual completion of the cut-off, but declared that the work would not be resumed until traffic conditions justify the outlay. The company's general program for the year is scheduled for confinement to actual necessities pending the announcement of the new government policy with respect to the railway situation in general, and in relation to encouragement of immigration in particular. In the event of the government not interesting itself in immigration the C. P. R. has already under way its own scheme for taking care of the problem. In this endeavor the company has approached the British government and has assurances of its support. It has been figured that if the government interests itself in immigration for agricultural settlers it will probably work in close conjunction with the Canadian National Railway System.

Additional Orders

The Algoma Steel Corporation report that their mills at Sault St. Marie have secured an order for 6000 tons of rails from the T. & N. O. and that with this, along with a number of other small orders they will be able to operate a single shift for two months. It is felt that by that time the railways and industrial plants will have started to place their orders for 1922 requirements, and business will be a bit more free. The Canadian Brakeshoe Co. Ltd., of Sherbrooke, report a very satisfactory condition of affairs, and state that the outlook for the coming year is good.

Steel sales in general have not amounted to a great deal this week. Prices remain fairly steady and some quarters show signs of weakening. Pig iron sales are conspicuous by their absence. The past week has been one of the dullest on record. Prices remain unchanged. The outlook is brighter this week and an improvement in the near future is looked for.

Machine tool sales are as dull as ever. There is nothing new to report in this line. An improvement is looked for in the spring but there is no immediate change of conditions anticipated.

The small tool and supply business is picking up a little, and promises to rapidly improve to a point where it was early in December, when it was noticed to fall off as shops commenced to close for the Christmas recess.

The non-ferrous metal market is very dull indeed. No activity is noted in any line. Aluminum continues to drop a little in price each week. In summing up, conditions are not as bad as they have been painted, and in a few months a much better tone will exist.

The Beaver Machine Shop, 1110 Center St., Calgary, Alta., are anxious to purchase a lathe and gear cutter. Particulars as to size, type, etc. can be secured by writing the above mentioned firm.

WERE WELL PLEASED WITH ANNUAL NUMBER

HAS our annual review number been the success we hoped for? Will it appeal to others as strongly as it did to us? Have we succeeded in preparing an issue that we can feel justly proud of?

These and many other similar thoughts came to our editorial mind after the presses had completed their work, and postmen all over the world were delivering our efforts in magazine form.

Naturally we were interested, for without an interest in one's daily task, nothing of importance can be accomplished. Fortunately our readers did not keep us long in doubt, for a regular avalanche of letters poured in congratulating us on the results attained. Lest we be accused of tooting our own horn, let a few of our friends blow it for us.

Edward Beck, secretary of the Canadian Pulp and Paper Association, says that he wishes to congratulate us on the very excellent number. He remarks that it is the best of its kind he has seen in a long time, and that it certainly reflects credit upon everybody who has had a hand in its production.

"I want to congratulate you on the excellent get-up of your issue," says A. E. LaBelle, vice-president of the St. Lawrence Flour Mills Co, and he goes on to remark that it is one of the finest trade magazines he has seen for a very long time.

H. S. Van Scoyoc, manager of publicity for the Canada Cement Co., says that we have certainly succeeded in making our number a very interesting one. "The varied information it contains," he continues, "should lead to its being preserved and frequently consulted during the year."

Frank Kennedy, manager of the Toronto section of the Bell Telephone Co., congratulates us on the number, and says that it has been perused by a number of their officials who are unanimous in their praise.

Thos. W. Gibson, deputy minister of mines for Ontario, says that our issue is a highly creditable one and must have entailed an immense amount of labor.

T. R. Deacon, president of the Manitoba Bridge and Iron Works, congratulates us on our enterprise, and says that the number is highly creditable and distinctly useful as it gives the viewpoint of so many men from so many different angles.

A. T. Enlow, president of the Dominion Sheet Metal Corporation, compliments us on what he terms the magnificent issue, and hopes that the returns will be sufficient to justify us in keeping up the pace which we have set during the last few years.

R. M. Hamilton, works manager of the Canada Machinery Corporation, congratulates us on the contents, and also makes mention of the cover design which he thinks excellent. We thoroughly concur with his views in this respect and the John Bertram Co., are to be congratulated on their aggressiveness and vision in presenting to the trade such an artistic cover. In fact, Mr. Hamilton says it is almost nice enough to frame.

L. T. Rutledge, professor of Queen's University, Kingston, congratulates us on the number and says he has been hearing compliments on all sides regarding the fine articles on economics and economical conditions.

Norman S. Rankine, special publicity agent for the Canadian Pacific Railway says that our special number is handsomely displayed and full of very interesting information. "I know from experience what a lot of trouble you must have gone through, in order to secure all the contributions from different writers of prominence," concludes Mr. Rankine.

Several managers of the different chambers of commerce, boards of trade, etc., in the various cities write in to say that the number appeals to them very much. W. R. Landon, of Chatham says that from an artistic and business standpoint the issue is a complete success. We could go on quoting what our many friends have told us, but sufficient has been recorded to show readers, and to convince us, that our efforts to please have most decidedly been appreciated. We can go on through the year 1922 with a firm determination to achieve still greater things, so that when 1923 rolls round we will be receiving fresh notes of appreciation on the progress made.

PERCENTAGE OF INDUSTRIAL BLIND

The American Engineering council have investigated the subject of eye accidents as a source of avoidable waste, and have found that the total number of industrial blind in the U. S. is 15,000 or 13.5 per cent. of the total blind population.

The eye it is declared is involved in 10.6 per cent. of all permanently disabling accidents. According to the report, eye accidents have been reduced 85 per cent. in some plants by the use of goggles. Sub-normal vision and faulty lighting are claimed to be responsible for the defects.

An examination of 10,000 employees in factories and commercial companies found 53 per cent with uncorrected faulty vision. Of 675 employees in a typewriter factory, 58 per cent. were found to need glasses. One estimate placed the loss due to faulty conditions above the entire cost of illumination. From 446 plants studied only 8.7 per cent. were in excellent condition, and the others were graded as follows: 32 per cent. good, 29.1 per cent. fair, 18.8 per cent. poor, 3.5 per cent. very poor, 7.8 per cent partly good and partly fair.

Improved lighting was said to increase output 2 per cent. in steel plants and 10 per cent in plants where the operations are on smaller pieces.

INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

Mr. C. Lovatt, 1537 St. Denis St., Montreal, Quebec, is in the market for one 25 h.p. steam boiler.

The Mount Royal Arena, Montreal, Quebec, is in the market for equipment for an artificial ice plant.

The Union Natural Gas Co., Chatham, Ont., are in the market for piping, tools, and drilling equipment for drilling wells.

Mr. J. Grey, Maple Street, Collingwood, Ontario, is in the market for equipment for a proposed steel spring and steel specialty factory.

The operation of the marking act has been postponed until after the next session of parliament, according to a report from Ottawa.

A Windsor, Ont., press report states that a city freight shed and steam truck are to be built there at an approximate cost of $250,000.

The Hamilton Tar and Ammonia Co., Lees Avenue, Ottawa, Ont., are in the market for tar stills, tanks and all machinery equipment for proposed tar and ammonia factory.

W. Ward & Son, 19 King St., London, Ontario, are in the market for machinery cutters' special equipment for the manufacture of cigars, to replace that which was destroyed by fire, estimated loss being $25,000.

The Rod Mills at the Sydney Steel plant, Sydney, N. S., will re-open the first part of next week, and the Wire Mill will start about the same time, according to the general manager of the Dominion Steel Corporation.

Grant Smith & Co., and MacDonell, Ltd. of Vancouver, have been awarded the contract for the construction of the extension of the T. & N. O. Railway from Cochrane 70 miles northward. The total cost of construction, including bridges, will not be less than $3,500,000.

The London division of the Canadian National Railways states that about 80 miles of track in this division will be re-laid with 100 lb. rails and that a considerable amount of other maintenance is planned for this year.

We are officially advised that the Grand Trunk Railway has ordered from the Algoma Steel Corporation, 30,829 gross tons of 100 lb open hearth steal rails. This is in addition to the 15,243 tons ordered from the Dominion Iron and Steel Company. The T. & N. O. Railway has ordered 6,000 tons of 80 lbs. open hearth steel rails from the Algoma Corporation.

The value of Canada's products of all forms for the year 1920 reached a grand total of $5,716,247,141, according to a report prepared by the Dominion Bureau of Statistics.

Authorized capital of $778,173,149 is represented by new companies in Canada, incorporated in the first eleven months of 1921, according to the Monetary Times. There were only six incorporations with a capital of $10,000,000 or over, against twenty during the first eleven months of 1920.

An Edmonton, Alberta, press report states that the Alberta government is negotiating regarding a market for Alberta coal, and that the Vancouver Harbor Commissioners are considering the construction of an extensive dock an which to store the coal for bunkering steamships, and that a similar scheme is proposed for Prince Rupert.

After being closed for over a year, the factory of the Central Spring Co., Oshawa, Ontario, started on January 9th, to get their factory in shape to resume operations as soon as possible. They will employ 20 men at the outset and expect in the very near future to have a full complement of 70 men working.

A further indication of gradual improvement in industrial conditions is contained in an announcemet that the Holmes Foundry Co., Sarnia, Ont., has taken back about 50 employees since the plant re-opened on January 1st. The superintendent stated that operations have been resumed, but that construction work on new units would not be carried on at present.

By the end of January it is understood that the island plant (Fort William) of the Canada Starch Co., will again be operating at full capacity and employing a full staff of 220 employees. As is usual during the months of December and January, the plant is closed for general repairs and stock taking but it is stated that orders are plentiful and when the plant starts next month it will be operated without interruption.

The Federation of British Industries with headquarters in London, England, has applied for space at the Canadian National Exhibition, Toronto, next summer. The Federation is an organization similar to the Canadian Manufacturers' Association in this country. It is affiliated with the Canadian body. The Federation has a membership of about $20,000,000,000 of capital engaged in British industries.

The ratepayers of Stratford, Ontario, have passed a by-law to spend $52,000 for a new wing to the General Hospital, and $47,000 for the Isolation Hospital.

Among the plants resuming operations at Hamilton, Ont., is the Burlington Steel Company. Mr. H. V. Hamilton announced that it would operate for the rest of the month at about 50 per cent capacity. Over 100 men have been given employment.

Preparatory to the commencement of building operations on the new five million dollar plant for the Western University, London, Ont., the board of governors have arranged for the enlargement of the new campus by the purchase of 30 acres of adjoining property. The site thus grows to 230 acres.

Power to spend $60,000,000 on roads will be adopted by the Minister of Highways of the Province of Quebec, at the present session of the legislature. Already the province has spent $30,000,000, but the additional amount is to be used to maintain existing highways and to build new ones.

The establishment of a chain of hospitals for crippled children throughout Canada and United States is projected by Rameses Temple, Mystic Shriners. This will involve an expenditure running into millions of dollars. A contract has already been let for the erection of a hospital in Montreal, which will cost $250,000.

A draft agreement with respect to the erection of a Union Station in Peterborough, Ontario, was reported on December 10th, to have been forwarded to the city council by the C. P. R. The proposed site of the station that has been agreed upon by the C. P. R., the C. N. Railways and the city council, is practically in the centre of the business section.

Official statistics just published show that whilst in Canada in 1919 there was one automobile to every twenty-five persons, there was one to every eighteen in 1920. The automobile industry employed 12,139 hands in 1919, turned out over 60,000 cars, and had an invested capital of $57,000,000. In the year 1915 Canada exported automobiles to the value of $3,000,000; during the year ended March 31st, 1921, the export value had risen to nearly twenty millions. Australia and New Zealand are said to be the best markets for Canadian made cars, although shipments are made to South Africa, India and the Dutch East Indies.

Sawyer-Massey plant at Hamilton have taken on 100 or more employees since January 1st.

The Toronto Carpet Co., according to Capt. S. J. Cragg, is finding business very good. The mill is working overtime.

Milton brick manufacturers this week announced a drop in their prices. The reductions run from three to four dollars per thousand. This should have a stimulating effect on the building prospects for 1922.

Persons desiring a copy of the form of certificate of origin required in the Bahama Islands for entry of goods under the preferential tariff as provided for in the Canada-West Indies Trade Agreement may obtain it on application to the Director, Commercial Intelligence Service, Ottawa.

A. W. Jackson, formerly with the Ontario Wind Engine and Pump Co., recently joined the traveling staff of the Steel Trough and Machine Co., Tweed, as their Ontario representative. Two other appointments: Robt. L. Welch for Montreal and Quebec, and C. B. Clarke for the Maritimes, have been made this year.

Preston & Schwartz, manufacturers of small tools, Galt, are adding to their line, drill press sleeves for Morse standard taper shank drills, also a range of combination centre drills. These are of tool steel with the relief ground after hardening. The firm claim to have perfected a machine for production of these tools.

R. J. Durley, secretary of the Canadian Engineering Standards Association tells us he has at his office, Room 112, West Block, Ottawa, the following publications which may interest our readers. Standard specifications for steel railway bridges, separate reprint of material specifications for above, requirements for distribution type transformers, also specifications for galvanized telegraph and telephone wire.

Charles Barber & Sons, manufacturers of turbines and power plant equipment, Meaford, Ont., have been sending their friends in the trade a very neat calendar for the New Year. The illustration is a reproduction of the famous picture of Canada's first parliament under Confederation and is most appropriate in that the Barber firm began business in this notable year, 1867.

The A. B. Jardine Co., Hespeler, are placing on the market a complete repair equipment outfit for garage purposes. It will include engine stand, floor and wrecking cranes, garage press, grinder, hand and power forges, and garage sets of taps and dies. The equipment, in whole or section, takes into practical consideration the varied requirements of the modern garage with the idea of improved practice and efficiency in view.

According to Business Administrator Pearce, the building programme of the board of Education for the city of Toronto, for the year, which in preliminary estimates calls for the expenditure of $2,711,700, will include $695,000 for High Schools. The total of nearly $3,000,000 required, also includes $1,338,000 to provide 92 grade class-rooms and $532,000 for the sites. Schools already under construction call for $56,700, and the High School of Commerce will have to be completed at the cost of $60,000.

The Holden Co., of Montreal, Toronto, Winnipeg and Vancouver announce that they have assumed control of the Canadian Brake-Shoe Co., Sherbrooke, Que., manufacturers of Electric Steel Castings. All business pertaining to the Canadian Brake-Shoe Co., will be transacted at the head office of the Holden Co., 354 St. James Street, Montreal, Que.

Prospects of Canadian export trade are more hopeful, as indicated by the marked increase in the number of trade inquiries published in the Commercial Intelligence Journal. In the current number no less than 65 inquiries for Canadian products—18 for food stuffs, 17 for hardware, machinery and metals, 19 for pulp, paper and timber and manufacturers thereof, and the balance for miscellaneous produce.

The output of coal from Canadian mines during the first nine months of 1921 was ten and three quarter million tons as compared with slightly over twelve million tons the corresponding period of 1920, according to a statement issued by the Dominion bureau of statistics. While the production was less than the previous year, it was greater than 1919, when the output of nine months period was 14 per cent less.

A large increase in customs received in Oshawa, has been recorded during the month of December, the figures showing them to be $236,050.83 as against $176,678.27 in November. This apparently shows that business in Oshawa is much better and more active than for many months past. With industrial conditions growing steadier and continuing to improve it is reasonable to expect that the receipts each month will soon equal the records of two years ago.

The International Malleable Iron Co., Guelph, are making a feature of their Imaco detachable maleable chain and attachments. The chain is described as being simple in construction, detachable at every link, interchangeable with all standard sprocket wheels, adaptable to elevating and conveying equipment, as well as agricultural and mechanical appliances. The range also includes a complete line of standard riveted drive chain, and elevator buckets for all kinds of work.

That many Canadian buyers will visit the eighth annual British Industries Fair, to be held in London and Birmingham from 27th February to 10th March, was the statement made in an interview by the British Trade Commissioner in this district. Buyers believe, said the commissioner, that a renewal of their overseas purchasing visits is due. This fair is Britain's annual display of her manufactures and industries and the trade buyers' opportunity of selecting goods for the ensuing season's trade.

Western Ontario is assured the construction of another plant by a United States firm. Dodd and Struthers, manufacturers of copper cable, have arranged for the early erection of a modern plant, the location for which has already been selected. Former Canadian exporters for the company were at Sherbrooke, Quebec, but in view of fast growing imports to this district the company opened a small branch at Walkerville in 1916. Increased Canadian business has proved to the company that a larger plant is needed.

The Newfoundland Government is negotiating with the Armstrong-Whitworth Co., of England and the Reid Newfoundland Railway Co., with regard to the previously announced project to create a water power development totalling 235,000 h.p. on the west coast of Newfoundland. This would be utilized for the establishment of a paper mill with a capacity of 400 tons of newsprint daily; a factory for smelting aluminum with a capacity of 15,000 tons yearly, and other industries.

Discussing the outlook of the New Year with The Montreal Standard, Mr. E. A. Robert, President of the Montreal Tramways Company, expressed confidence in Canada's ability to continue upon normal lines of development, in respect to industrial, financial and agricultural affairs. He foresees no reason for pessimism, on the contrary, he believes that the Dominion has come through a year of unprecedented world difficulties with considerable credit. "Immigration, curtailment of unnecessary imports, and American capital," said Mr. Robert, "are the essentials requisite to a further enhancement of our national development along sound lines."

The Premier and the Minister of Public Works for the Province of Ontario, will decide next week regarding the T. & N. O. extension. Between two thousand and three thousand men will, in all likelihood, be employed on this project and already a staff of about 100 are on the job above Cochrane. Thirty-five were sent up this past week to work on the survey. It is expected that when the contract is let and operations begun on a larger scale, the extension will be instrumental in relieving the unemployment situation in Ontario to a great extent. Another interesting item is to the effect that nearly 200 of the T. & N. O. employees who were laid off on Friday previous to Christmas for a general stock-taking have returned to work. to be completed at the cost of $60,000.

Large export outlet for motor cars of Canadian manufacture opens up a promising field for the motor industry in this country. Export business in automobiles, as well as in other lines, is coming back gradually after the collapse of the international trade in 1920. In the past five years Canada has advanced rapidly as an exporter of motor vehicles. It is not necessary to delve into specific details, suffice to say that the value of cars exported in the year 1921 totalled approximately $33,000,000. The total

amount of cars exported in the year 1915 did not exceed $5,000,000. A visit to the General Motors Corporation plant at Oshawa makes it apparent that a healthy amount of business is existent. Some departments are working on double shift. Over 1,700 men are employed at Oshawa. Close to 800 men are employed at Walkerville. The number of plants are kept busy supplying materials and parts. The total investment in plant, inventory, etc., of the corporation's plants in Canada approximates $20,000,000.

The industrial development in Sherbrooke, Que., has been satisfactory from many points of view. The completion of the new plant of the Canadian Connecticut Cotton Mills, manufacturers of tire cotton fabrics, represents an investment of over $5,000,000 and in normal times will give employment to over 2,000 employees. The new plant of Julius Kayser and Company, was completed in 1921, and their production consists of high grade silk gloves, hosiery and underwear represents an investment of over $3,000,000, giving employment to about 1,000 employees. The Super-Heater Co., manufacturers of Super heaters for locomotives, marine and stationary boilers; number of employees 160, cost of plant $260,000. The extension of the Sherbrooke Machinery Co., manufacturers of pulp and paper machinery was erected at a cost of $100,000 and will enable this concern to double its production, number of employees 100. The new plant of the Pressure Proof Rings, Ltd., manufacturers of piston rings, was also completed in the year 1921, at a cost of $25,000, number of employees 25. Within a short time there will be another new industry in Sherbrooke, the Canadian Vesta Battery Co., manufacturers of automobile batteries, this being an additional link in making Sherbrooke an automobile centre. At the present time they have large factories manufacturing automobile tires, tire cotton fabrics, rubber accessories and piston rings. The above mentioned firms are only a few of an extensive list which has been published in Sherbrooke daily papers.

THE PREVENTION OF FREIGHT LOSS AND DAMAGE

(Continued from Page 27)

with the freight claim agents, particularly on roads having supply train service and reclamation or testing plants.

They can use their scrap material, empty corrugated, and other containers at large stations which need it for coopering purposes. If they have a treating plant, they can see that treated ties are not loaded in good box cars.

They may be able to induce manufacturers to discontinue nailing the floors of four-wheel warehouse freight trucks. If these floors were bolted, freight would not be damaged by nails which work up in service. They could look into the seal question to be sure that agents do not carry too large a stock of seals. If an agent has much more than thirty days' supply, there is a big chance for misuse. The telegraph department can help by watching advance notices on stock, rush car orders concerning live stock and perishable, and in the matter of mailing diversion or stop orders, if, through error, that is done. They can check against errors in transmission of consists, icing reports, diversion orders, etc.

They can help educate operators to keep dispatchers posted in detail when a train is being delayed at their station. They can help educate operators to be on the look-out for dragging brake rigging, or hot boxes on passing trains. The traffic department can help educate shippers to keep posted on car loading rules and classification requirements. Anything they can do to induce large receivers of freight to maintain a written record of all freight delivered to them without regular billing so the claim agent can check against this record in handling claims for short packages, will go a long way to reduce short package losses.

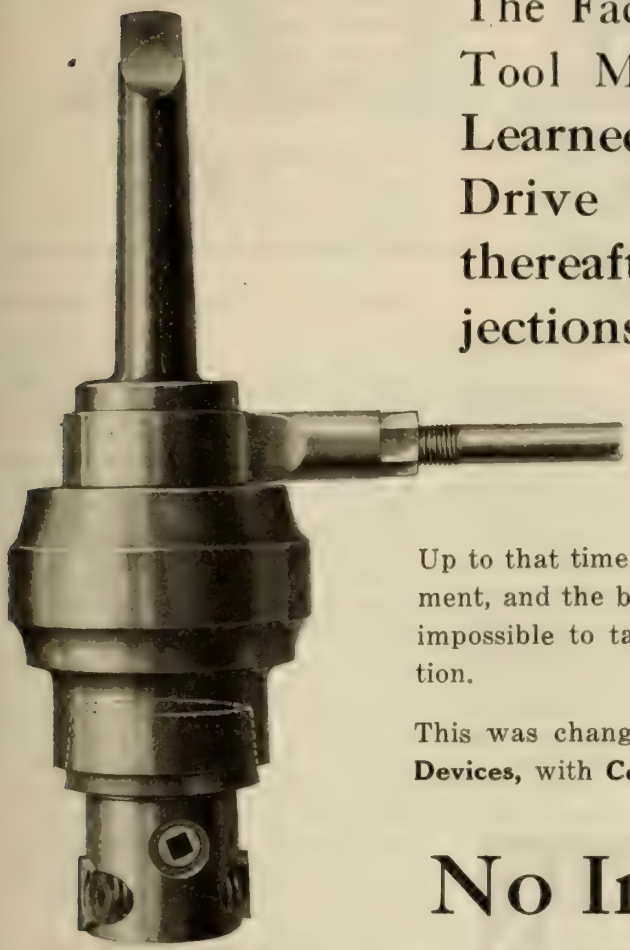
Get Shippers Interested

They can help shippers get interested in existing laboratories for the study of proper box construction. Many shippers do not know that the average box fails first at the nailing points—that a few more nails in the right place make a stronger box. They can encourage shippers to study the causes for their claims, recording them by causes and specific articles, by having customers or salesmen report conditions as determined at destination with apparent cause, so they can learn what may be necessary to ride it safely—the railroad will help in this.

They can get the chambers of commerce interested in spreading the gospel of careful marking and packing, and in the study of how the shipper and carrier can handle freight without damage. They can advertise claim prevention along with passenger and other advertising, because claim prevention means good service, and the claim account which represents failure in service sums as much as the entire expense of the traffic department as just shown.

The police department, of course, is engaged in property protection, but I often wonder if they are intensively pushing the matter of correct seals and seal records, bad doors and door hasps. Their influence will go a long way to keep this situation in the clear. They can't do business without a good seal record and a proper facility upon which to apply the seal. If there is a scale department on the railroad, anything they can do to help keep country wagon scales in proper shape, by educating owners in their use and upkeep and by doing the same thing with elevator people and other users of scales, will be of great help. Careless weighing and scale maintenance is the crime of modern business. In the general work to reduce costs, both the railroad and express employees have found they must work together to get the bests results. An express man should be on every local prevention committee.

In many instances, the same problems must be overcome; for example: —On ventilation and refrigeration—on hand freight or express—short packages—it is just as important to police express resting on a truck as it is to police freight resting on a platform. It is just as important to keep express trucks from contact with trains at station as it is to watch baggage trucks. Express must be protected from the weather the same as baggage and freight. Delay problems apply to both. The same study of classification requirements is necessary. Packing, marking and billing have many points of similarity.



Yardmasters and engine foremen are as interested in switching express cars as freight cars, and for the same reason—to avoid delay and rough handling. The car department is interested in defective express equipment the same as freight cars. And an express car can be set out en route the same as a freight car for the same reasons—defective running gear, hot box or other bad order condition. The baggage department is in on this, because often one car is used for both express and baggage, and the same general troubles encountered by baggage are with express. Good containers are of importance to both branches of the service.

Particularly can the two branches co-operate on the question of preventing pilferage and robbery. By all means, express and railroad men should work together locally and nationally in the effort now being made to reduce transportation expenses, and every branch in transportation service get busy with all the means at their command to produce the best service possible at the least cost.

SIMPLE HYDROHOIST

One of the simplest forms of pump consists of an endless chain in the links of which, owing to their peculiar shape, the water is trapped and raised. The mechanism, in fact, operates as a water hoist. In order to make it more efficient a British firm has introduced a very ingenious modification. A wire rope is used, and on this rope are threaded a series of small steel cups, each with a thimble at its centre to keep it at the right distance from its neighbors. When the rope runs at 600 feet per minute this hoist will deliver 3,500 gallons per hour. Curiously enough this delivery represents more than a solid column of water of the diameter of the cups. The cups rise full of water, and there is in addition a large quantity carried on the outside. No fixing is needed beyond the casing at the wellhead, and on this and the grounds of simplicity and ease in maintenance the "hydrohoist," as it is called, appeals particularly to agriculturalists.

Worked Like Magic

Note the dotted lines illustrating position and size of friction Cone.

The Factory Manager of a large Tool Manufacturing Concern **Learned of the Jarvis Friction Drive Tapping Device and thereafter there were no rejections.**

Up to that time they had been using regular standard equipment, and the bottoming taps did not bottom. It was almost impossible to tap the holes so that they would pass inspection.

This was changed like magic when the 20 **Jarvis Tapping Devices,** with **Cone Friction Drive,** were installed.

No Inspection Needed

The Jarvis Friction Tapping Device taps the holes to bottom, and then runs in a second time to do its own inspecting, and, when it finishes, every hole is thoroughly cleaned out to bottom.

Very little pressure is needed to drive the Device.

The Drive is controlled by pressure on the machine spindle.

Stripped threads are unknown.

Holes tapped in toughest metal with little tap breakage.

Standard Chuck.

No special taps required.

The Tap is freely started and stopped while rotating.

Adaptable to Drilling Machine or Speed Lathe.

Ask us about the Jarvis High Speed Tapping Devices, which act without clinching or binding.

And the Jarvis Quick Change Chucks and Collets, for Drilling, Counterboring, Tapping and Stud Setting.

BUSINESS PAPERS EXTREMELY VALUABLE

IT WAS the reading of a business publication that inspired Henry Ford to quit the farm and seek employment which would help him to build a "horseless carriage" such as he then read about. It was by reading a business publication that George Eastman got the idea of establishing what has become by far the greatest establishment of its kind in the world. It was the reading and studying of business writings that started Frank A. Vanderlip on a career which landed him in the presidency of the largest national bank in America. Edison reads more business periodicals and books than perhaps any other man in America; he assured me that he couldn't afford not to.

Cyrus H. K. Curtis once told me, continues an editorial in Forbes Magazine, that he first conceived the idea of creating the Saturday Evening Post when, as a youth, he read a story about a young man who achieved dazzling success in business. It was reading and studying the business achievements of John D. Rockefeller that fired James B. Duke with ambition to become in tobacco what Rockefeller had become in the oil industry.

Only the other day a salesman of one of the many business "courses" now in vogue, told with great gusto that he had just sold his "course" to the president of a very large railroad, Daniel Willard, of the Baltimore & Ohio. J. Kindleberger, the famous paper manufacturer, tells how the reading of a business book caused him to organize what became a very successful enterprise.

Recognizing the infinite value of business books, "Forbes" has decided to open a new department to encourage the reading and studying of them by those who are ambitious to make headway in the world. As one means of emphasizing the benefits which can be derived from business books, they are offering $250 in prizes for letters answering the question, "Which Business Books Have Helped You Most, and How?"

It has become not uncommon, concludes the article, for employers to get a line on the kind of reading done by employees being considered for promotion. I once heard of an employer who made an excuse to visit the home of an employee whom he was thinking of promoting, but when the only reading matter within sight was a popular weekly and second-rate fiction, the employer concluded that he had better promote someone who devoted at least part of his spare time to reading periodicals and books calculated to widen his knowledge of his business and broaden his mentality.

The man who reads this story is to be congratulated, because he too is a reader of a business paper, and is thus building upon a solid foundation.

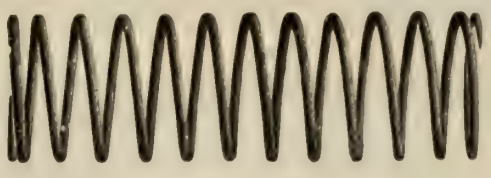
U. S. ELECTRIC
Drills and Grinders
Can be Attached to any Lamp Socket

For drilling in metal these drills are the superior of every other kind of portable drill. Their operating cost is only half that of air drills. And they can be attached to any lamp socket.



A trial will prove that our drills and grinders will save you time, labor, and expense. Order a few to-day.

Made in several sizes from 3-16" to 1¼". Motors wound for alternating or direct current or both, 110 or 220 volts.

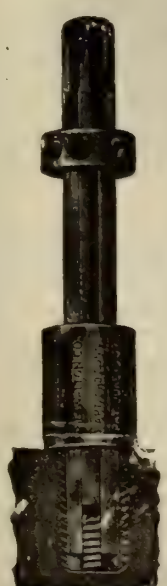
Manufacturers of

HIGH GRADE SPRINGS, CARBON OR VANADIUM STEEL, BRASS OR BRONZE.

Our excellent facilities for the production and heat treating of Springs insure accuracy and durability.

Write for catalogue, also free engineering service on your spring problems.

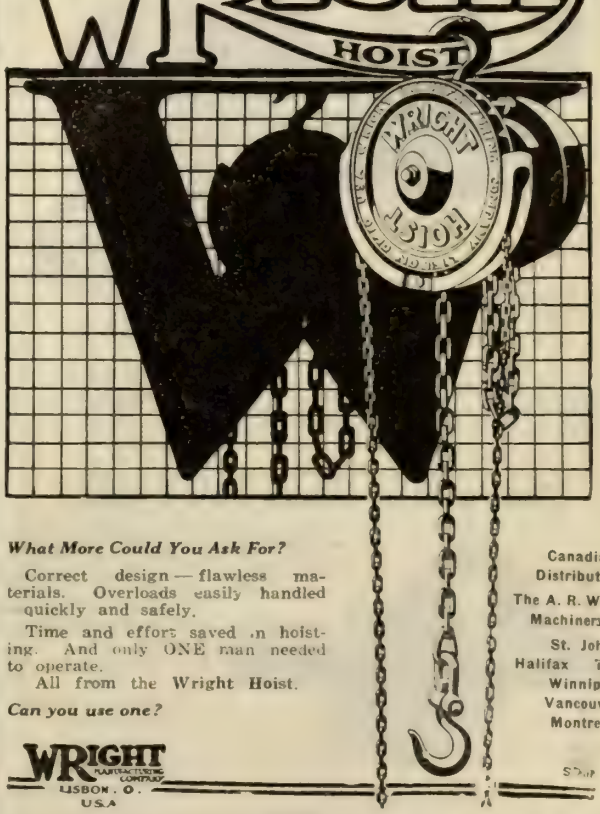


Raymond Mfg. Co., Ltd.
Corry, Pa., U. S. A.

Buried in the Work and Broke!

Next time a tap breaks below the surface of a large casting, don't let some makeshift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

Walton it Out in a Jiffy



And save the casting.

Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

Sixty-day trial offer proves the Walton Extractor pays for itself. Write.

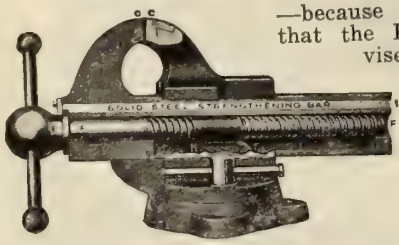
PARKER VISES



Built to Stand the "Gaff"

Eighty years of vise making has solidly convinced us that, after all, nothing stands the heavy strain of daily use like vise castings of the right mixture of Bessemer steel and grey iron.

They "GRIP LIKE A GRIZZLY"

That's Why They Sell Easily

—because it is well known that the Parker is a "he" vise for heavy work. Write for folder and dealer offer No. 12.

One of the "70"

The Charles Parker Company Master Vise Makers, Meriden, Conn., U.S.A.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

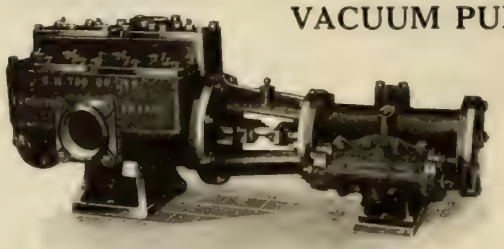
Main St. W., Hamilton

FIFTY YEARS OF QUALITY

Hand Protection

Means Better Work

Mitten StyleNo. 681



Steel-Grip WORK MITTENS

and work gloves give complete hand **protection** plus hand **comfort**. The same reinforcement (small steel ribbons over strips of tough leather) that protects the hand also gives so much extra wear that these mittens and gloves last almost indefinitely. Sewed closed with steel thread, they are absolutely rip-proof. The steel reinforcement does not interfere with flexibility. Your workmen equipped with Steel-Grips will dig in with a will.

Write us to-day for suggestions on your hand protection problems. We can save you money on your work glove purchases.

Industrial Gloves Corporation
424 Wellington St., W., Toronto

HEPBURN PATENT VACUUM PUMP

The Advantages of A Self-Draining Pump

Be sure your pump is self-draining like this Hepburn Patent Vacuum type. The steam ports are located at the side of the cylinder and the water is automatically drained off at each stroke. The design of the water end provides access to each valve without disturbing the pipe connections. Full strokes and steam economy are the result.

Let us quote on Engines, Cranes, Winches, Power Presses, Planers and Castings.

GALT, ONT.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

Canadian Machinery BUYERS DIRECTORY

If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index—last page of book, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

How About Your I.Q.?

An I.Q. is an abbreviation for "intelligence quotient" and is the basis on which psychologists, doctors and teachers are estimating how Canadians rank, all the way down the line from genius to morons and idiots.

Dr. C. K. Clarke, noted Canadian alienist, says that not more than twenty per cent. of Canadian children have more than average intelligence. Is your child one of the average sixty per cent.? one of the twenty per cent. above this line? or one of the twenty per cent. below? How do you rank yourself?

Perhaps you think you are normal, but an investigation of this article of Dr. Clarke's may give you a rude shock. Get your family and friends studying it and see where they rank.

This remarkably timely article appears in

MacLean's Magazine *for* JANUARY 15

The West Is Still There!

***By* Charles Christopher Jenkins**

A staff writer of MACLEAN'S MAGAZINE was sent West a few weeks ago to find out what there is to these 'blue ruin' stories. He returns with a huge grist of facts, and reports that, although hard hit in many ways, the West is, as everyone who knows it would expect, breathing the virile and vigorous spirit of constructive optimism.

Included in this article are striking and timely messages to the readers of MACLEAN'S from Hon. T. C. Norris, Premier of Manitoba; Hon. W. M. Martin, Premier of Saskatchewan; and Hon. Herbert Greenfield, Premier of Alberta.

"Have confidence in us; we'll come through!"—this is the key-note of an article for which Mr. Jenkins travelled nearly ten thousand miles to get definite and accurate facts for MACLEAN'S readers.

Other Big Fact and Fiction Features in this issue of MacLean's:

CANADA'S CARIBOU CROP—Vilhjalmur Stefansson argues that reindeer-steaks will soon find their place on the menu of thousands of Canadian families.

WHAT CAN THE MOVIES TEACH?—Nicholas North's investigation of the "Menace" of the movies; they should be excellent educators.

THE SAIL DRAGGER—by Frederick William Wallace. The first installment of a three-part novelette written by a Canadian who knows, loves and understands the sea and can tell a vigorous, dramatic tale.

THE PIPES OF DEATH—an exotic and thrilling story of a little-known country by "Sapper"—H. C. McNeile.

THERESE AND GERMAINE—An Arsene Lupin detective-mystery story, from the fertile pen of Maurice LeBlanc.

CONVERTIN' ELDER HAWKINS—Archie McKishnie returns with the first of a new series of Lenix Ballister negro stories.

MOSTLY SALLY—Pelham Grenville Wodehouse's cheery, rollicking serial.

And in this issue there is a particularly strong **Review of Reviews Department**

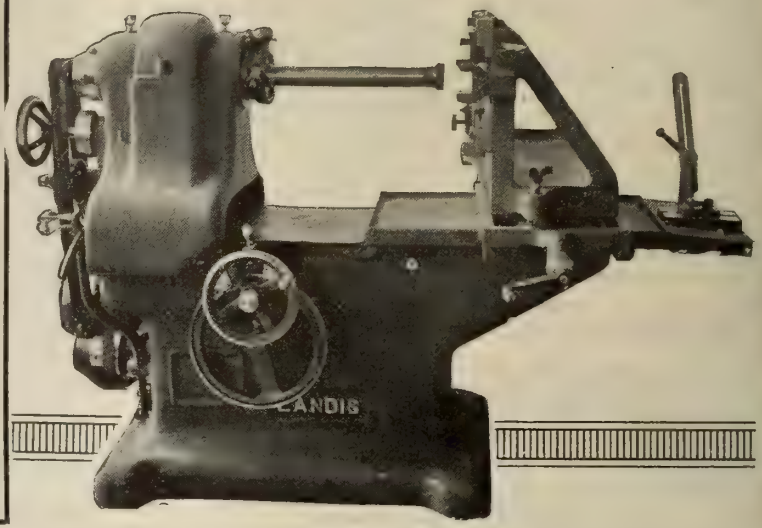
No Vertical Adjustments

Cylinder Grinding has grown to such proportions that it occupies a very prominent place in the grinding field. The most accurate equipment must be used and a quick set-up obtained in order to produce the highest quality of work in record time.



The Landis No. 5 Cylinder Grinding Machine is built to handle all makes and types of motor blocks cast singly or *en bloc*. The cylinder holes are properly located with the center of wheel rotation by the centering device. This is only one of the many exclusive features in a *Landis Cylinder Grinder*.

May we describe to you some of the other interesting features?

P & W

Pratt & Whitney Taps

"With the 'Con-eccentric' Land"

P & W Taps are **Good** taps—easily the best where accuracy and high speed are essential. They cost more to buy, but less to use than others.

If you're doing work that calls for big production and for unusual precision, give them a trial. You'll be back for more when you see them prove themselves.

The "con-eccentric" land — the special feature of Pratt & Whitney Taps, permits sharpening on face of the cutting edge without affecting size. It lengthens life and assures accuracy hitherto thought impossible in a commercial tool.

A 144 PAGE BOOK---Free

Written *by* and *for* Engineers

This latest edition has been completely revised—new material inserted, new repair problems described.

The Smooth-On Instruction Book No. 18 is the most valuable book of its kind. Its 144 pages contain sound practical and money-saving advice on various power plant and boiler room repairs. Its compilation has been contributed to by engineers the country over.

Your copy is waiting—all we want is a word from you and we will send it along.

Bliss Knuckle-Joint Embossing Presses

Simple, Compact and Powerful, these presses are built in a great number of sizes and capable of pressures ranging from 30 to 1,500 tons.

Specially adapted for embossing silver, brittania, brass, copper, etc., in the manufacture of medals, coins, regalia, jewelry, watches, silverware, etc.

After looking over your work, write us your requirements.

No. 198

THE BRITISH GOVERNMENT

(DEPARTMENT OF OVERSEAS TRADE)

announces that the eighth annual

BRITISH INDUSTRIES FAIR

will be held at

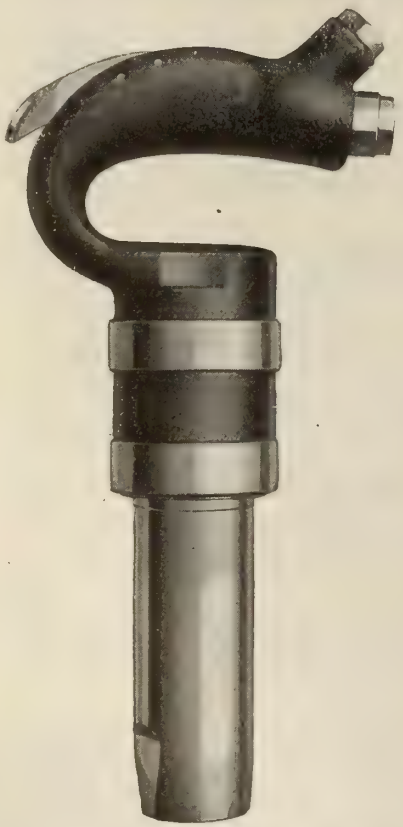
LONDON and BIRMINGHAM

from

27th FEBRUARY to 10th MARCH, 1922

All Canadian buyers are cordially invited to attend

A particularly fine and comprehensive range of



GENERAL MACHINERY, FOUNDRY APPLIANCES & SMALL TOOLS

will be shown in addition to many other lines of manufactured goods.

Goods can be examined, values compared and contracts concluded at the Fair with the minimum of trouble and the greatest saving of time.

Full information and complimentary admission cards are obtainable from:

H. M. Senior Trade Commissioner, 248, St. James Street, Montreal.
H. M. Trade Commissioner, 260, Confederation Life Building, Toronto.
H. M. Trade Commissioner, 610, Electric Railway Chambers, Winnipeg.

CLEVELAND "FOUNDRY" CHIPPERS

Are Dust-Proof *Easy To Hold* *Easy To Control*

A Remarkable Tool for Fast Chipping

Made in "Seventeen" sizes with "Open" or "Enclosed" handles—
Outside or Inside Latch.

CLEVELAND FOUNDRY RAMMERS

For Floor - Flask - Bench or Core Work

Run Fast Hit Hard

Have No Vibration

Cleveland Rammers Are "Dust-Proof"

They cost less for "Up-Keep" than any Rammer made.

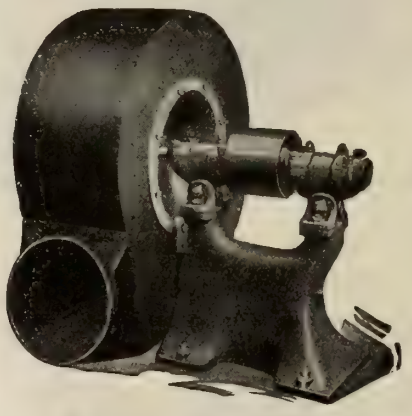
The Canadian Standard Reversible Mill Exhauster will keep your shop clean, remove sawdust, shavings, fumes, gas or any loose materials and disagreeable odors.

Insurance rates can be reduced; floors and machines covered with sawdust, chips or shavings, increase the fire risk.

Insurance companies reduce the premiums where adequate precautions have been taken to prevent fires.



Blast Wheel — This wheel is so constructed that it will handle any kind of stringy material efficiently, such as sawdust, shavings, cotton lint. Will also handle gases, fumes, smoke, etc.

The Canadian Standard Planing Mill Exhausters have reversible housings so that the outlet can be adjusted instantly to any angle desired.

This eliminates necessity of crossed belts. Simplifies changes on alterations in piping or building.

The housing is of heavy rolled steel plate securely bolted together with angle irons, round cast iron outlet bolted to the housing. Blast wheel mounted on heavy cast iron spider.

Every fan carefully tested by running test at speeds in excess of that required.

Dominion Oxygen is ready for you any time, at any place, in any quantity

THE Dominion Oxygen Company, Limited, has fulfilled its promise to Canadian Industry.

Already four of the modern distributing centers called for in its building and distribution program are in operation, and Canadian-made oxygen of the highest and most uniform purity is available in sufficient quantity to supply the entire Dominion.

Co-ordination of production and distribution has made it possible to ship orders on the day of their receipt—insuring prompt delivery to all parts of industrial Canada.

An exceptionally light and strong type of cylinder has been adopted which greatly reduces freightage and handling charges, while insuring a gas content sufficient to make constant reorders unnecessary.

Unfailing and uniform purity, always reliable immediate service, a conveniently handled cylinder of large gas capacity and a liberal policy of cylinder loans make Dominion Oxygen and Dominion Oxygen Service the choice of Canadian oxygen users.

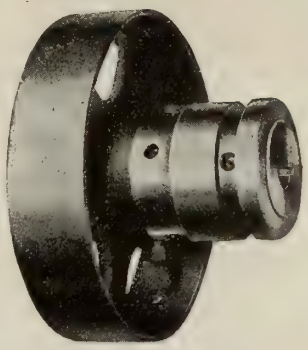
THE JOHNSON FRICTION CLUTCH

Friction Clutches From Stock



Johnson Clutches, both single and double, can now be obtained from stock in our standard slow speed type to fit all common shaft diameters and all standard pulley bores, within the range of light and medium horse powers that we cover.

State definitely —

Just what the clutch must drive.
Actual maximum horse power.
Speed of clutch shaft.
Diameter of shaft.
Diameter, width and bore of pulley.

We Will Select the Proper Clutch and Make Immediate Shipment on All Ordinary Requirements.

Friction Control Means Better Machinery

And the Johnson Clutch is supreme among friction clutches. Adopt it as your standard — always dependable and always promptly obtained.

Complete engineering service to consult on your problems and to handle special installations of any kind.

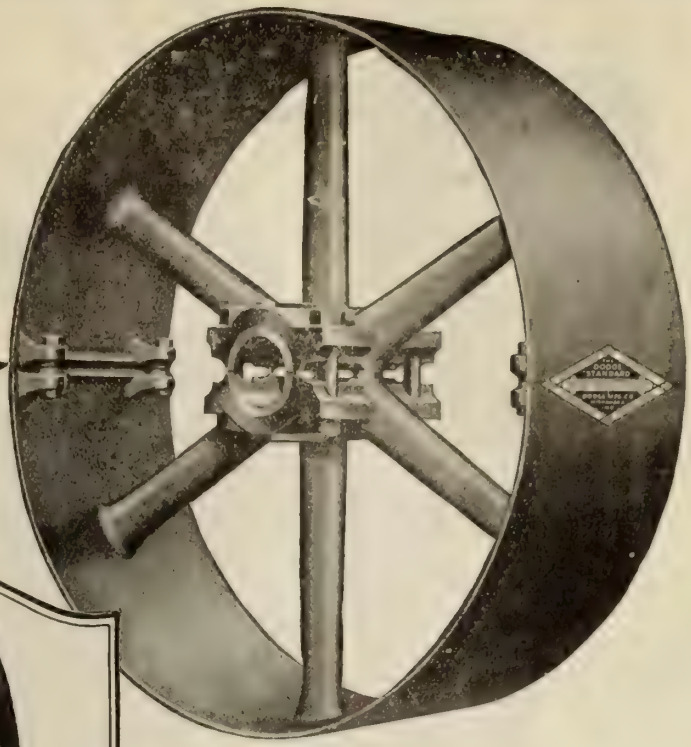
When labor is expensive, there is all the more reason to use efficient tools.

Much time and effort can be wastefully expended on a filing job.

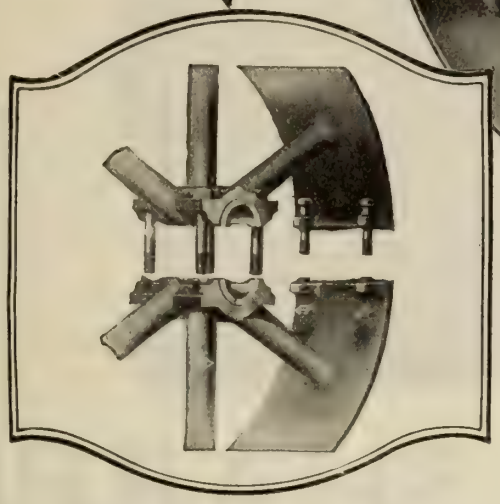
If, at each stroke, a file does not cut keenly, discard it and buy a new one.

Watch for the least loss of efficiency.



And insure maximum cutting-service by specifying one of these brands:

Kearney & Foot
Great Western
American
Arcade
Globe



Made in Canada by

Nicholson File Company

Port Hope - Ontario

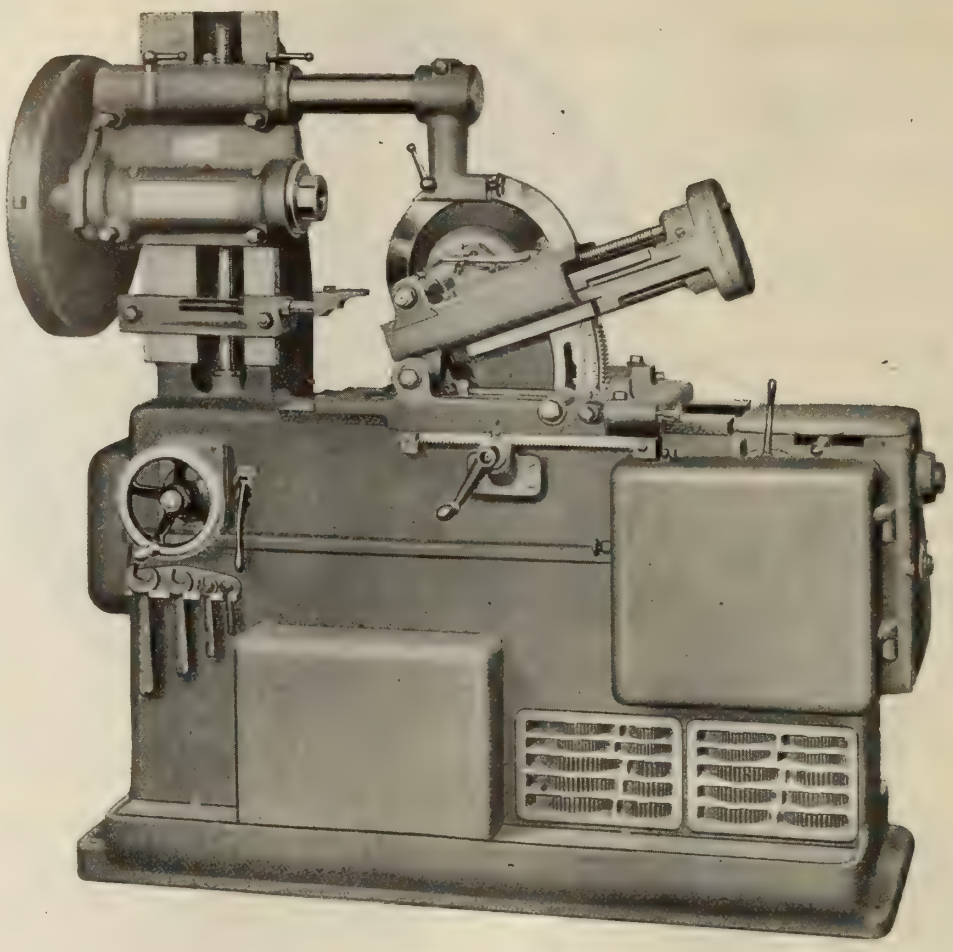
Rim edges are fractured, then drawn together by bolts through rim lugs. A perfect joint.

A split iron pulley for hard service

built by

DODGE

Under particularly trying conditions, in damp places or in chemical plants where acid fumes prevent the use of wood pulleys, the Dodge Standard Split Iron Pulley will deliver continuous efficient service.



These pulleys are moulded from metal patterns, cast of the highest grade of grey iron, accurately faced on the rim and lacquered. These careful methods produce a pulley that is absolutely round and in perfect balance.

Contour and balance are permanent—cast iron is non-flexible.

Split construction obtained by fracturing the rim affords easy installation and when installed and the draw bolts tightened, the result is a perfect joint.

Dodge Manufacturing Co. of Canada, *Ltd.*

Head Office and Works: Toronto, Ont. **Eastern Branch: Montreal, Que.**

BROWN & SHARPE

No. 13 Automatic

Gear Cutting Machine

THIS machine, adapted to cut both spur and bevel gears and clutches, offers many advantages to shops of various sizes. To the owner of the small shop, the investment value of a single machine adapted to the cutting of both spur and bevel gears is apparent. This machine is dependable, can be quickly set up, and left to complete the gear while the operator gives his attention to other work.

For the larger shop, a machine of this type could form part of a battery of spur gear cutting machines and be available for the occasional bevel gear or clutch job which would not warrant the purchase of a special machine adapted to cut bevel gears only.

Manufacturers and users of machinery with sizeable repair shops will find this rapid, accurate machine valuable in emergency repairs where either spur or bevel gears must be rapidly cut to keep machinery running.

Write for Specification Sheets describing this Machine

Elements of Machine Design—Lesson No. 5

Classification of Fastenings—Types of Rivets Used—Riveted Joints and Factors Which Must Be Considered—How Rivets Should Be Placed—Shearing, Crushing and Tearing Possibilities

By L. T. RUTLEDGE

A FASTENING is a mechanical device for use in machines, structures and instruments to clamp or secure pieces and members together. They may be permanent, temporary, rigid or flexible, and can be divided into three main classes each having its own special characteristic and function. These are as follows:—

(1) Riveted connections.

(2) Threaded or screw connections.

(3) Keys, cotters and pins. The above will be discussed in the order given.

Rivets and Riveted Connections

A riveted connection is a permanent fastening removable only by destroying the rivets that constitute the fastening. In cases where steel members such as structural shapes, plates, etc., are to be joined together, the riveted connection is the type of fastening used. The mechanical student, no doubt, will be more interested in riveted connections used in the construction of boilers, tanks, steel cars, machines, etc., but the same general theory applies whether the connection belongs to a bridge or a steam boiler.

It is unnecessary to describe a rivet. Every mechanic is familiar with the term, but to make sure that the types in use are understood we illustrate in Fig. 24 three styles, viz., the steeple and core head, the button, and the countersunk head. The dimensions are given in relation to diameter "d" the size of shank before riveting.

The steeple, or sharp pointed rivet is one easily formed by hand riveting but it is weak to resist tension. The cone head is one of great strength and is much used in boiler work. The button head is used to a large extent in structural work. The countersunk head is only used where space for the head is lacking, but it weakens the plate to a great extent.

The Author is Professor of Mechanical Engineering at Queen's University, Kingston, Ont., and should any reader wish help in any problem on mechanical matters, Mr. Rutledge will be only too pleased to offer assistance. To save time, write direct to Kingston, explaining your trouble in detail.

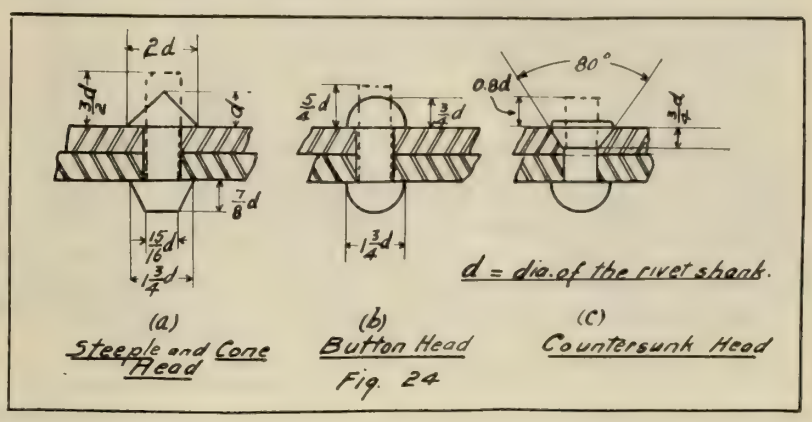

Fig. 24

Rivet Holes

Rivet holes may be either punched or drilled, but of course a drilled hole gives a much better job as it does not injure the metal around the edge of the hole to the same extent as punching. Rivet holes are usually made 1/16in. larger than the shank of rivet for the better class of connections; but in heavy structural work a clearance of ⅛in. is allowed.

This allows for inaccuracy in laying off the holes and punching. It is always anticipated, however, that the hammer blows fill the rivet shank to the size of hole, for to be effective, the rivet must be perfectly tight against the hole.

Types of Joints

The following is a general classification of riveted joints:

(1) Joints met with in the construction of pressure vessels, such as boilers and tanks, in which an internal pressure is resisted, and leakage overcome.

(2) Structural joints similar to the ordinary riveted type of a bridge. Resistance against leakage is not a factor to be considered.

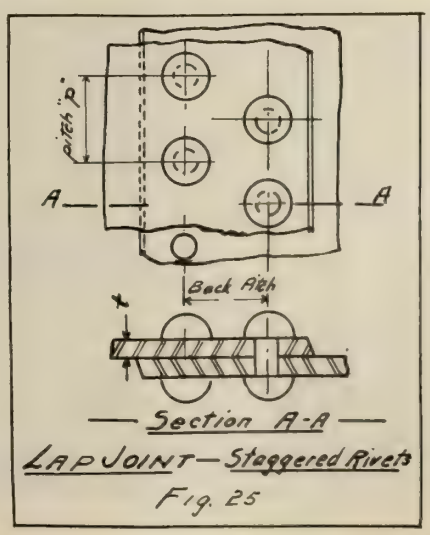

Fig. 25

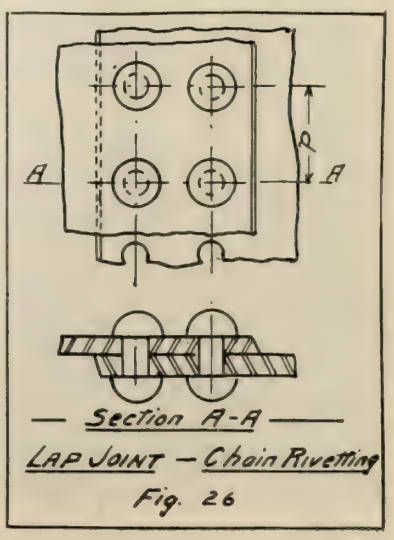

Fig. 26

(3) High-class joints such as are used in the construction of hulls of ships where great strength, stiffness, and durability are required, as well as precaution against leakage.

The following is a particular classification:—(1) Lap joints; (2) Butt points.

Figures 25, 26, 27 and 28 illustrate and explain the chief characteristics of these two types.

Riveting may be done in single, double or triple row as the load demands. Rivets in two adjacent or parallel rows may be opposite one another, as in chain riveting, fig. 26, or they may be staggered (or zigzag) as in fig. 25. In the case of butt joints, the plates which are butted together may be held by one strap, or by two straps, one on each side. In fig. 28, towards the end of this artcile, we show a triple riveted double strap, butt boiler joint. This is the most efficient joint in use and an analysis of it is made to determine its strength and efficiency in every particular.

Strength of Joints

In the design of riveted joints and the analysis of stress in them, the following nomenclature will be adopted:

d=diameter of rivet shank.

d'=diameter of rivet hole.

t=thickness of the plate used in construction.

t'=thickness of cover plates or straps.

p=pitch of rivets, which is the distance between two adjacent rivets in the outside row.

s^t=unit stress in tension.

s^s=unit stress in shear.

s^b=unit stress in bearing or crushing.

E=efficiency of the joint.

P=resistance against failure or the strength of the joint.

The units of measurements used are the inch and pound.

Rivets should always be placed at right angles to the force causing them to fail, that is, they should be subjected to a shearing or bearing stress only. If tension occurs at all, the permissible stress is quite low, about 7000 pounds per square inch.

A joint may fail by the following causes:—(a) shearing of the rivet:—

In a simple lap joint the rivets tend to shear at one section, generally on the contact line of the plates as illustrated in fig. 27 (c). This is called single shear. In the case of a butt joint with two straps, the rivets are in double shear since failure can only take place along two sections. It takes twice the load to cause failure in double shearing: therefore, it is apparent the resistance against this danger is twice that against single shear. The single shearing resistance of a rivet is the area of its cross-section multiplied by the unit stress in shear.

$$\text{or } P = \frac{\pi}{4} d^2 S_s \text{ ----(33)}$$

The safe single shearing value of a ¾-inch wrought iron rivet, whose cross-sectional area is .4418 square inches, is .4418 x 10,000 or 4418 pounds, where 10,000 lbs. per sq. in. is a safe shearing unit stress. Its strength in double shear is 8836 pounds.

(b) Crushing of the Rivet on the Plate

The rivet may fail by the load causing it to crush against the plate. The crushing force is distributed over a semi-circular area. However, it is customary to take the area resisting crushing to be the thickness of the plate, multiplied by the diameter of the rivet. This method really considers only the component of the pressure parallel to the force upon the rivet.

The resistance to this failure is:

$$P = tdS_b \text{ ----(34)}$$

The bearing or crushing value of a ¾-inch rivet against a ½-inch plate, for example, using the usual safe bearing value of 20,000 lbs. per sq. in. is

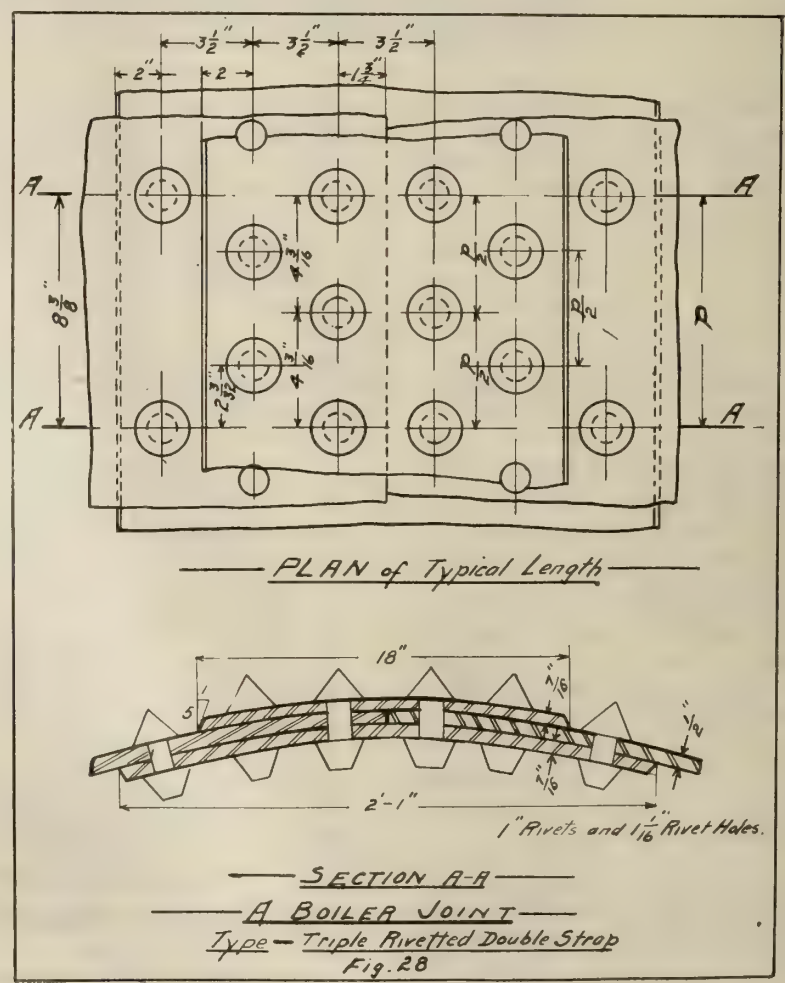
½ x ¾ x 20,000=7,500 lbs

Some designers use, instead of the diameter of the rivet, the diameter of the hole in the plate. If the rivet completely fills the hole, this latter method is more exact. The use of the rivet diameter is to be preferred, however, since it is the safer value.

(c) Tearing of the Plate Between Rivet Holes

In a riveted joint subjected to tension, the plates may tear along the line of the rivet holes as shown in fig. 27 (a). The length of metal between two rivets in a row is equal to the pitch less the diaemter of one rivet hole. The resisting area is t (p-d') and the resistance against failure is

$$P = (p-d')tS_t \text{ --(35)}$$



(d) Failure of the Margin

If the rivet is placed too close to the margin of the plate, failure may occur by a piece of plate of width equal to "d" pulling out, as shown in fig. 27. (e). For this to happen, the plate would have to be sheared in two places. If "y" is the distance from the centre of the rivet to the edge of the plate, the resistance against this method of failure is

$$P = 2ytS_s \text{ ---(36)}$$

The margin may tear out along one section as is illustrated in Fig. 27 (d). Formula (37) has to be modified to suit this case. To guard against marginal failure, designers usually provide a

Using Gravity to Speed up Production

Watching Handling Time—Grouping of Machines and Operations Essential—Flexibility of System Advantageous—Transporting Material From Different Floor Levels

By J. H. MOORE

"WE MUST reduce operating expenses and increase production." This, in a nutshell, is the trend of thought being expressed by business men all over the world. There are many ways of reducing the cost of production, one of which is the rapid movement of material. Nothing ties up a product like poor handling facilities, and in many cases this cost is greater than the operation itself.

The foreman in charge, or whatever executive handles such work, should ascertain how much time is consumed on actual manufacture, then investigate the percentage wasted in handling. For example, a man at a machine might consume 4 seconds obtaining a piece of work, 3 seconds for the actual operation, another four to dispose of the piece, showing that 8 seconds is consumed in handling, against 3 for actual manufacture. This incident may seem an exceptional one, but in actual experience it is often found that 90 per cent is lost by careless handling of the product.

In the July 31st, 1919, issue of Canadian Machinery we published an article on Shop Transportation, which covered various methods of speeding the work through the plant. In the present material we will confine our remarks to gravity conveyors only.

The Gravity System

Lest there be any not thoroughly conversant with the gravity method of conveying, we perhaps had better explain that this system takes the form of a series of rollers, which together form a conveyor. Each roller is mounted on a ball bearng, which of course makes them sensitive to movement. The free power of gravity is used, giving the system its name.

We will not attempt to describe the many uses of such conveyors, for practically any product having at least one flat surface can be carried successfully. Two features which make this production aid a great convenience are its flexibility, and compactness. The gravity method is as flexible, if not more so, than any railroad track, and owing to the small space necessary, the conveyor can run between machines, around columns and obstructions without trouble.

The percentage of production gained depends largely on the type of installation used. In every case the sequence of operations should be carefully planned. The product should be kept travelling in one direction, as far as possible, that is to say, no jump backs should be tolerated. Shift the machines if necessary, but keep the work moving steadily.

Fig. 1 shows how the Buda Engine Co., use gravity conveyors to advantage. They have arranged their machines in such a way that each operation follows in proper sequence. Thus the operator merely places his completed part, so far as he is concerned, on the convey-

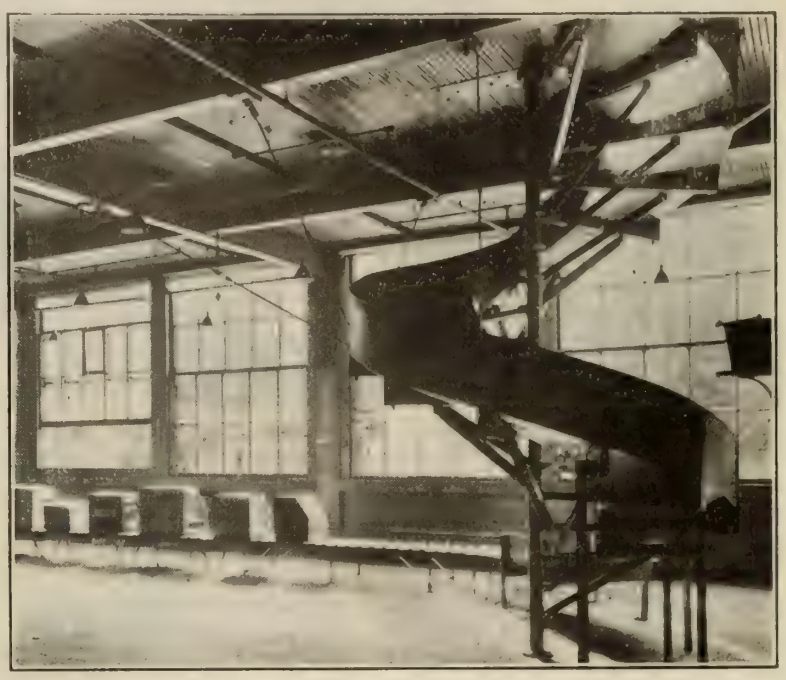

Fig. 3 — Showing how spiral chute can be used in conjunction with conveyor.

We are indebted to the Mathews Gravity Carrier Co., Port Hope, Ont., for Figs. 2, 4, 5, 6 and 7, also to the Lamson Co., Boston, Mass., for Figs. 1 and 3.

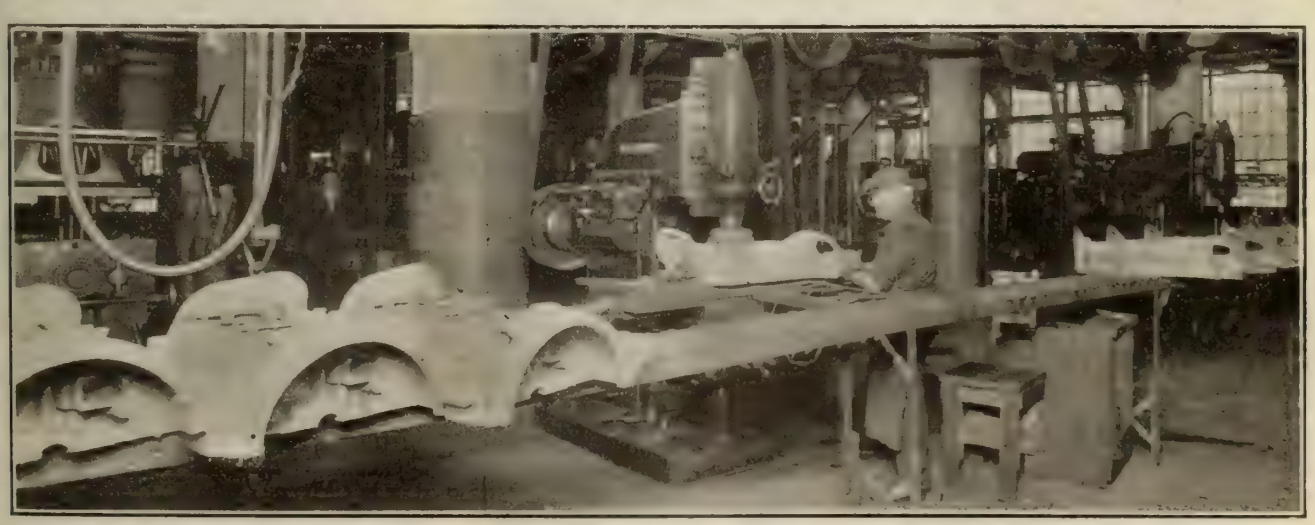

Fig. 1 — Showing how a number of machines may be linked up by means of conveyors.

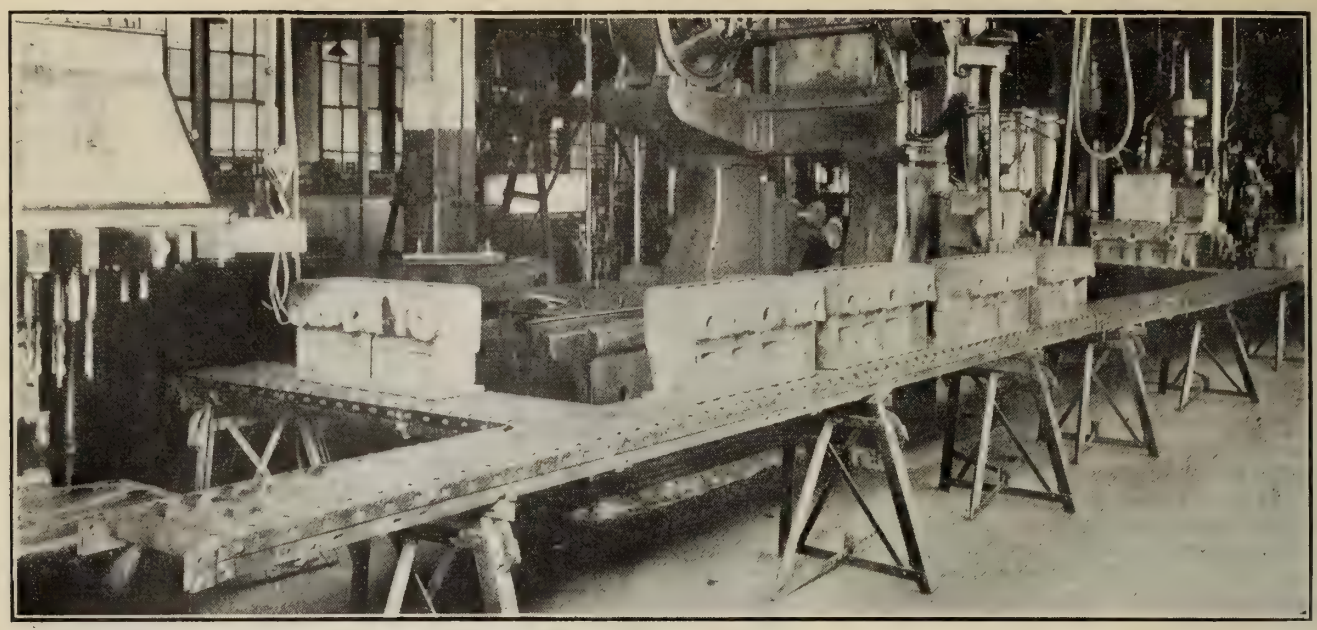

Fig. 2 — The Packard Motor Co. find many uses for such conveyors as shown in photograph

or and picks up another piece. Since installation, the stock in process, formerly piled on the floor at each machine has been eliminated, also the production time has been correspondingly lowered.

The Packard Motor Co., find this type of conveyor very useful. Fig. 2 depicts one line of track in use, and it will be noted that every s ooften, other tracks at right angles to the main line are arranged to carry the work in other directions. Again we see the advantage of careful planning of machine tool equipment for the operations in this factory are arranged in such a way that the parts keep moving forward.

In many cases it is desirable to transport material from one floor to another. This is easily accomplished by a spiral-conveyor of the type shown in Fig. 3. The National Cash Register Co. make use of this instal'ation for conveying boxes to waiting freight cars, and while this is a very important function, it is only one of many uses to which this style of chute can be adapted.

The first operations can be started if possible at the top floor, the product gradually working its way down until it reaches the cars. At each floor the material can be directed to other machines, or if desired, it can be kept on going down any number of stories. It all depends on the arrangement, which again emphasizes the flexibility of the system.

It is futile to a'tempt a description of the many uses of gravity conveyors in the machine shop, but here is one exam-p'e. The Domestic Engineering Company, Dayton, Ohio, use this s'yle of aid for transporting their Delco light outfits to the shipping pla form. The crates are bolted to the skids as the machines pass along. This method naturally saves time and labor. The shipping address is also stenciled while the product is, so to speak, on the move. The crated machines are then conveyed direct to the waiting car or delivery truck as the case may be. What holds true in this example can be applied in a multitude of ways to machine shop in general.

Good use of separate portable sec tions, or a complete installation can b made in any foundry. For example tak Fig 4. The pigs can be taken direct from the car to the pile without undu effort on the workmans' part. Thi naturally speeds up the work and re duces cost of handling.

Not only can this type of conveyo

Fig. 4.—A conveyor of this nature reduces considerable manual labor.

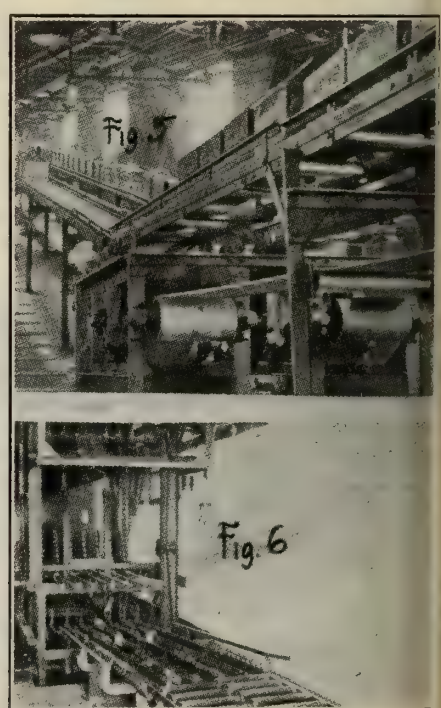

Fig. 5 — Showing portion of very large belt co veyor. The photograph shows two of a seri running in both level and inclined positions. Fig. 6 — Double roller gravity conveyor connect to an automatic straight lift elevator. Larg heavy shipping cases are handled on th system.

Fig. 7 — The small shops will find this idea particularly valuable.

be used in the yard, but inside the plant as well. Core shops find the method useful for conveying cores from the bench directly to the oven, and from there to the foundry.

In the plant itself the castings as they come from the molds are placed on the conveyors and transported to the cleaning room, later moving into the factory. Flacks are also moved around by this system, in fact the conveyor is used for all foundry purposes.

Automotive Field

The automotive trade owes much to this method of conveying. Many parts are handled efficiently that previously were a deficient problem until gravity was used to speed up production. Even complete automoble bodies can be easily transported, so that the system is by no means confined to small parts.

The wire mill industry finds this method to be ideal for the moving of bales and rolls of wire of all kinds, in fact, there is practically no industry which cannot use the system in some form or other.

Merchandise of all kinds can be carried upwards as well as down, but of course in such cases power units must be operated in conjunction with the gravity in order to form a complete conveying system. These lifting or carrying up units can vary in character, depending upon requirements. Belt, chain, apron or straight life elevators can be used, the product settling the type necessary.

Fig. 5 shows a portion of a large belt conveying system and it will be noted that a series of belts is running in both level and inclined positions. Fig. 6 depicts how the straight lift type of elevators is used, and in this case heavy shipping cases are handled. Fig. 7 tells its own story, and as we could illustrate hundreds of uses, we had better content ourselves with the views shown. Every industry finds its own particular adaptation, but all secure the same results, viz, a decided reduction in handling costs.

LESSONS ON MACHINE DESIGN

Continued from page 18

marginal distance equal to from 1½ to twice the rivet diameter. The greater value should be used on riveted joints of pressure vessels.

Design of a Riveted Joint

In the foregoing section, some important equations which are applicable to simple joints, were given. It should be recognized that the main object in a design of this nature is to make the joint equally strong against tearing of the plate between rivets, shearing of rivet, or crushing of rivet against plate. Assuming a lap joint with plates of equal thickness, and assuming that the joint is safe as far as the margin is concerned, then for equal strength the values of "P" in equations (33), (34) and (35) are equal. To determine the proper rivet diameter and the proper pitch of rivets, the three equations may be solved simultaneously. Equating

$\frac{\pi d^2}{4}$ to $2dtS_b$ we get

$$d = \frac{4tS_b}{\pi S_s}$$

Equating $\frac{\pi d^2 S_s}{4}$ and $(p-d')tS_t$ and assuming $d = d'$ we get

$$p = d + \frac{\pi d^2 S_s}{2tS_t}$$

Equating $2dtS_b$ and $(p-d')tS_t$ and as before assuming $d = d'$, the pitch becomes $p = d + \frac{2dS_b}{S_t}$

The above calculations would, in all probability, give a rivet of some odd diameter. It would be necessary to select a commercial size of rivet. This would, of course, destroy the equality assumed at the beginning.

Having selected the commercial size of rivet to be used, the pitch can at once be determined. In general, the method of procedure in designing a riveted joint, having been given the thickness of plate, is as follows:—

Sketch a joint that experience suggests will be suitable for the design in hand. Select a commercial size of rivet in keeping with the thickness of the plate. Consult the handbook while making this selection. Determine and list the expressions for all possible methods of failure. Determine the minimum resisting strength of the joint as far as shearing and crushing are concerned. Determine the proper rivet pitch by equating the minimum value already found to the value of the resistance against tearing of the plate between rivet holes.

Using the minimum value of the strength of the joint, as designed, determine the efficiency of the joint, which efficiency will be the ratio of the minimum value to the strength of the same length of solid plate.

$$\text{or } E = \frac{\text{minimum } P}{tLS_t} \quad \text{---- (37)}$$

Where L is a unit representative length of joint.

News From the Welding Field

Importance of Autogenous Pipe Welding

Machine Operated Blowpipe Can Sometimes Be Used More Economically Than Hand Torch—Application of Hydrostatic Tests —Demonstrations of Strength of Welded Pipe Joints

By H. G. IGLEHART

THE welding of non-fired pressure vessels, though it is practised to a very considerable extent, seems to be somewhat shrouded in mystery. A clear understanding of its great advantages is not at all general, even in the engineering profession. As you all know, the most important parts of non-fired pressure vessels are the piping and fixtures, inclusive of connecting joints. Referring to the construction of such parts, one frequently hears engineers say that this, that or the other pipe must not have any welds. They are never able to give any satisfactory reasons for their views. Their answer, in every case, is equivalent to a plain "because"

This lack of understanding is very largely due to the fact that welding engineers and manufacturers of welding equipment have not given the subject of pipe welding sufficient publicity to acquaint potential users with the possible applications of the process and with approved practices in fabrication and installation.

There are still many who look on a weld in a pipe as a patch, yet who would not hesitate to insert a pair of screwed flanges with a gasket and bolts at the very point where welding is unwelcome. The flanged connection certainly has no higher strength efficiency than the welded joint, and it costs more to install, more to cover, and will ultimately prove a source of overtime for repairs which, in some instances, may require shutting down of the plant during busy periods. It is obvious, therefore, that the welded joint is more desirable in these respects, and I may add that it contributes to greater general safety.

There are several operations in pipe welding for which there should be specially designed machines. In acetylene cutting, for example, a machine operated blowpipe can be used much more economically than the hand cutting torch because of its greater speed, both actually and compared to the volume of gases consumed. The machine operated blowpipe also admits of far greater accuracy, thus reducing setting-up operations to a minimum and contributing to faster and better welding. The development of special machines should receive the united attention of oxy-acetylene welding instrument designers, machine builders, engineers, and pipe fabricators, for the purpose of bringing forth new and better mechanisms and appliances as rapidly as possible.

Pipe Welding

We will now take up a comparison of a plain butt weld and a regularly flanged joint. (See Fig. 10.) The flanges may be counterbored and peened; they may be rolled or expanded type, plain like a boiler tube or with grooves turned in the flanges; they maye be threaded only or threaded and peened, or of various other types, any of which forms can use rolled steel or cast iron flanges on steel pipe, but a lot of bolts and gaskets, are required to complete what when finished can only be a temporary splice, as everyone knows of the expense and exasperation of maintaining gasket joints. The welded joint, when properly made is as neat appearing as the pipe itself, does not interfere with hot or cold insulation and will not require any attention during the entire life of the pipe line, as a good weld does not deteriorate any faster than the parent metal.

To make such a weld properly the ends of the pipe should be chamfered at an angle of 45 degrees and be placed in line with the tips not less than one-sixteenth of an inch apart in order that

Author presented this matter before the Convention of the International Acetylene Association at New York.

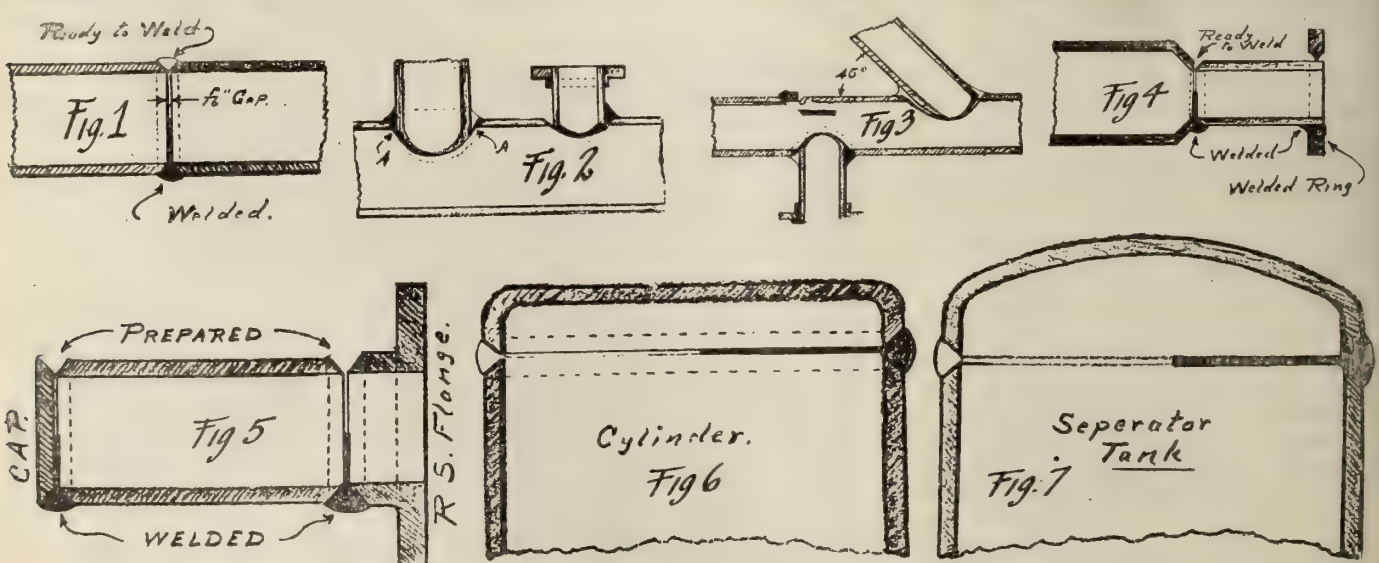

Fig. 1 — Plain butt weld on pipe line. Fig. 2 — Design for welding branch lines. Fig. 3 — A smaller branch requires shorter ends on the neck. Fig. 4—Preparation of ring welding flange. Fig. 5 — Hub welding flange. Fig. 6 — Cylinder head flanged. Fig. 7 — Cap both dished and flanged.

thorough penetration may be had to the inside of the pipe, which must be religiously done in all cases if the 100 per cent. mark of strength and efficiency is expected. The welding rod or wire should be of as near the same carbon content as the material in pipe as can ordinarily be had. Much depends on the welder, as no carelessness or guessing must be done in regulating flame of torch. The weld should be built up as rapidly as the molten metal can be handled without overlapping and in a continuous operation all around the pipe. If the welding flame is slowly moved over the first part welded for a few inches, the weld is automatically and homogeneously annealed for all practical purposes.

Hydrostatic Test

After completion of weld a hydrostatic test should be applied to at least double the working pressure to be carried. While the pressure is on, a vibration test should be added by free use of a medium hand hammer in striking sharp blows all around the pipe on each side of, and close to, but not on the weld. That will show up porosity or cold shuts, by removing the small particles of oxide which, in many cases, temporarily prevent leaks from showing up during tests in which vibration is not applied. The idea of not hammering directly on the weld is that in doing so it sometimes happens that a thin shell is forged over small leaks which will soon corrode away when the weld is in use and then a leak gives another black mark against welding, although it should be charged to the method of testing instead of to the welding profession.

A comparison of a welded neck or branch line, as from a header, and a regularly flanged tee with its gasket joints is not necessary, as any one can readily see. Regarding the welded neck or branch line (See Fig. 2) the operation requires a male and female cut, both of which should be machine made, when a machine can be built. The hole should be cut at a good wide angle in order to form a good groove for the weld. The neck or branch must be cut so that it conforms to the inner contour of the main or header.

The end of the neck or branch line will not require any bevel or chamfer at its short points, as there it goes through the other pipe, but at its long points it must meet the inner and outer face of main, therefore gradually lessening towards the short points. This would not be the case if the neck or branch is of smaller diameter than the main or header, as you can note by reference to Fig. 2 or 3, the smaller the branch compared with the main, the shorter will be the ends on the neck and less bevel at the long points.

Clearance Essential

Note that the hole must be cut so that when set up ready to weld there is the required one-sixteenth inch clearance at all points, points A A included. In welding it is, of course, impossible to make a thorough amalgamation with all of the fibre layers or courses of the neck or branch at points A A. Extra strength must be added by building up the weld to form a good fillet to a radius of about twice the thickness of the pipe. I have been referring to a 90 degree branch, but, except for the shape of cuts, it all applies to any angle branch line or neck. A neck should never be welded on and then have centre cut out afterwards unless it is short and of not less than 14 inches diameter, so that the end can be welded over after the cutting has been done; otherwise the weld will be a poor one and have a low efficiency. The testing of such welds, or in fact any pipe welds, should be as described for plain butt welds.

Very frequently flanges should be and are welded on necks, branch lines and main lines and headers. Sometimes screwed flanges are used and simply welded on the back as a sure seal, but usually they are of the rolled steel hub, or ring types (See Fig. 4). The plate shows a ring welding flange which is prepared by boring to exact size of outside of pipe and then chamfering each side to a 45 degree angle to centre. They are welded with a small fillet on the pipe side and straight on the face side, allowance being made to reface the entire flange after welding and before testing.

Hub welding flanges (See Fig. 5.) simply have a hub forged to practically same inner and outer diameter of the pipe; the end of the hubs are chamfered, thus the weld becomes a regular plain butt weld and is treated the same in every way.

Pipe With Closed End

Quite often the end of a pipe is to be closed with a welded plug or cap, as it might be called. (See Fig. 5.) The picture shows the best form of getting the most strength at reasonable cost in sizes up to 6 or 7 inch, provided, of course, the pressure to be carried is not too high, in which case it would be necessary to dish the cap. In some cases it is found better to make the cap flanges as shown for cylinder head at Fig. 6. The size of the pipe and the pressure to be carried have to be the governing factors in deciding the best and most suitable form for this work, as some cases require a cap or plug to be both dished and flanged, as shown at Fig. 7.

A welded separator or receiver head is by far the most serviceable when done as illustrated in Fig. 7. Steam separators are subject to sudden and frequent changes of temperature, causing terrific strains and stresses, with the result that riveted and caulked heads soon get to leaking in the joints and around rivets. The writer has had this very forcibly driven into memory by several severe experiences, which fact makes it a joy to say that no leaks or trouble of any kind have arisen from the numerous welded dished and flanged heads now in use, some of them being on very high pressure and high temperature work.

There are many people even in these modern times who will say "a welded pipe is all right if one only could be sure it is strong enough to be safe." I pity their mental condition. We cannot afford to break everything to pieces to ascertain its strength. We have the same methods and ways of testing the strength of a pipe weld as of any other article made by welding or otherwise. To substantiate these statements, I will describe some parts of a series of research operations carried out in the shops of the W. K. Mitchell Company in Philadelphia this year for the purpose of demonstrating and illustrating that welded pipe joints are strong when properly made. Early in the year the Power Piping Society requested the W. K. Mitchell Company to supply it with some data on tensile strength tests of welds shown porosity and crystallizatests was made. Following are condensed memoranda of findings:

Result of Tests

All specimens were cut from a length of 8-inch, 28½ pound steel pipe. They were 13 inches long and 2¼ inches wide, and milled down in centre to about 1½ inches in width for a clear length of 6 inches. A greater length could not be used in the machine at that time, but, of course, a 17-inch length would give greater accuracy in yield points and elongation.

The longitudinal strips without any welds averaged 57,625 pounds tensile strength. The longitudinal strips were for grip of testing machine. This flattening was done under steam hammer, cold. Longitudinal strips with oxy-acetylene welds in centre averaged 55,895 pounds breaking strength, or an efficiency of 97 per cent. Longitudinal strips with d. c. electric welds in centre not flattened except at extreme ends averaged only 44,245 pounds, being an efficiency of 78 per cent., the broken welds shown porosity and crystallization, a poor grade of welding wire having been used by mistake. The longitudinal strips were welded before being cut up into the 2¼-inch strips. Circumferential strips were welded after being cut off and straightened.

The straightening was done by slow pressure, the strip being heated to a dull red. Circumferential strips free of any welds or joints averaged 59,125 pounds tensile strength. Circumferential strips with the regular mill lap in centre averaged a breaking strength of 57,975 pounds, an efficiency of 98 per cent. Circumferential strips with oxy-acetylene welds in centre averaged 58,385 pounds, or an efficiency of 99 per cent. The circumferential strips with d. c. electric welds in centre averaged 54,515 pounds, being an efficiency of 92 per cent. All welds were made from outside of pipe only, as would be done in regular practice. You no doubt will have noted that the circumferential

strips averaged about 4½ per cent. stronger than the longitudinal specimens. Possibly the heating for straightening affected it some. That is a metallurgical question rather than one of welding.

For the sake of complete information, a few specimens were welded from both inside and outside. The breaking of them showed no gain at all in the strength, which proved that the pipe welded from outside only secures all of the obtainable strength. Many of the previously mentioned breaking tests did not break in the weld or close to it, which shows they often reach the full 100 per cent. mark.

A few months ago a number of practical demonstrations of strength welded pipe joints were made under the direction of the writer at the W. K. Mitchell Company shops in Philadelphia. The test pieces were later cut into sections for close examination and are still on exhibition at the Mitchell Company offices. Photographs were taken at the time, some of which are shown in this article. We took a piece of 6-inch pipe, about six feet long, with two four-inch branches welded in. One piece was old and rusty, the other was new. They were on exact opposite sides of the 6-inch pipe and about three feet apart. The six-inch pipe was clamped to a bending table, two eye-bolts attached to the branches, and they were then pulled up by use of a crane, no filling being in pipes. The old one cracked at an angle of 30 degrees (See Fig. 8); the new one developed a small crack on back at angle of 47 degrees. The cracks are about 1½ inches long. The old one went through at one point; the new one goes only one-third the way through. The sections of this weld show it would not have leaked with a water pressure of 500 pounds per sq. in. See Fig. 8, then Fig. 9 and note how the six-inch pipe was crushed, giving indisputable proof of the great strength of acetylene welded pipe joints. No heat was used when pulling.

We next made a regular butt weld in seven feet of 8-inch F .W. pipe. This was sand filled and regularly bent hot to a radius of 30 inches, then flanged and tested with 750 lbs. hydrostatic pressure. No leaks or any signs of distress appeared. Fig 10 shows the result.

We now took a piece of pipe made of four pieces of 8-inch F. W. pipe, with a flush butt weld in centre having a bored-out coupling slipped over it and welded at its ends. To the left was a regular threaded joint, with several reinforcing welded tacks. To the right as a regular butt weld. This was sand filled and "regular bent" hot on a thirty-inch radius as shown at Fig. 11. The two outer welds were cut away and the remainder of the bend flanged and tested to 750 lbs. cold water pressure. No leaks or defects appeared, but even so, this form of joint is not generally recommended, as it is expensive, being virtually three welds for one; and then there is an element of risk, by reason of the unavoidable strain of unequal expansion of the pipe between two welds and the coupling or sleeve, as the sleeve is of much larger diameter and would have a much lower temperature in any steam line.

We also took a 7½ feet piece of 8-inch F. W. pipe with a six-inch neck welded in. This was filled and bent hot on a thirty-inch radius, the neck being on the outside of the bend, causing a fearful strain on all parts of the welded joint. No rupture occurred, simply a slight elongation of the lower end of the six-inch neck, due to the natural stretch of the 8-inch, as you will note a Fig. 12.

We also had a number of fuel oil heater coils for steamship ballast tanks or special oil tank steamers. They were of two-inch extra heavy pipe. Each coil had fifty-one feet, four inches of pipe, with from two or three butt welds, made before bending. The bending was done hot, but without any filling in pipe. All were tested to 300 pounds cold water

Continued on page 26

Practical Ideas from Practical Men

A MODEL LOCOMOTIVE

By R. H. TANNER

Believing that readers of Canadian Machinery will be interested in a model locomotive which I have completed, I append the following information regarding this engine. The photograph is self explanatory in so far as the exterior appearance is concerned, but in order to allow some conception as to the actual size of the model, I might add that as far as I possibly could I erected this locomotive to a scale of 1½ in. to the foot.

The length over all is 7 ft. 6 ins. The boiler shell is made from 5-16 in. plate, other parts including cab, fire box, etc., being 1-16 in. thick. The tender is made of 1-8 in. material and holds approximately 7 gallons of water. Over two hundred 3-8 in. rivets are used on the boiler, this portion being 8 in. diameter, and holding a pressure of 110 lbs. when in use.

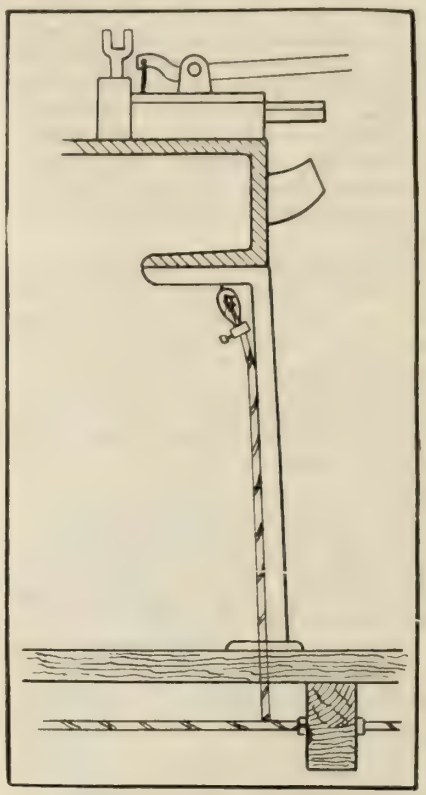
The cylinders are 1 7-8 in. bore, 2¼ in. stroke, and the driving wheels are 7½ in. diameter. The bogie and tender wheels are 3½ diameter, and as will be noted the double type of truck is used. There are sixteen ¾ in. tubes in the boiler and when the engine has steam up has a capacity of pulling 1½ tons. The pump supplying the boiler runs off the back axle, and other interesting features include sight feed lubricators, whistle, pop safety valves, electric headlight, etc.

The model has a full Walschert movement, and all operating levers are duplicates of the actual locomotive. I built this engine simply as a hobby and it has taken, roughly speaking, about five years of my spare time. I have a small lathe, shaper, and drill fitted up in my back shed and the enjoyment I get from these few tools is well worth while. Incidentally I made the shaper myself, this having an 8 in. stroke.

Editor's Note:—Mr. Tanner enjoys his model making, and tells Canadian Machinery he is always learning something while amusing himself. How many others make good use of their spare time? For the best three letters telling us "How readers have made the most of their spare time," we will award a prize of a steel scale enclosed in leatherette case. The closing date of this opportunity is Feb. 16th. Write us now.

TWO VALUABLE IDEAS

By D. A. H.



A four-slide automatic spring machine is used by a certain manufacturer of mouse traps to form a rather intricate spring used on one of the traps. Anyone who has had experience with this type of wire forming machine or in fact, with the simpler ones, knows that, while they are great producers, they are prone to little troubles—in fact, they are like automatic screw machines and other automatic machine tools in that they rarely run an hour without requiring some little attention at least.

This machine is no exception, though of the best, and it was placed in the best lighted spot in the factory so as to offer all assistance to the operator. But at least half the interruptions require him to look or work under the machine.

Now the under side of every machine is dark and a workman gets along if possible without hunting up an electric light extension, plugging it in, and working with one hand while he holds the light with the other. This thing was done in the trap factory hundreds of times—sometimes feeling in the dark and at others spending the time to get an inconvenient light. But the owner finally hit upon a scheme that is saving him time and money and giving him better results.

He tapped the lighting circuit in the floor and ran a flexible tube up in the corner of one leg, placing a 40 watt lamp at the top. It's the best thing I have seen. All the workman does is to turn the key and the under side is as bright as day. No delay, no trouble, no light to hold, no light to smash. It saves its cost every month.

After the war, first increased demand and then the competition price adjustment caused this same owner to want greater production from his spring machines. He had been running them for years at the maximum speed recommended by the machine builders—

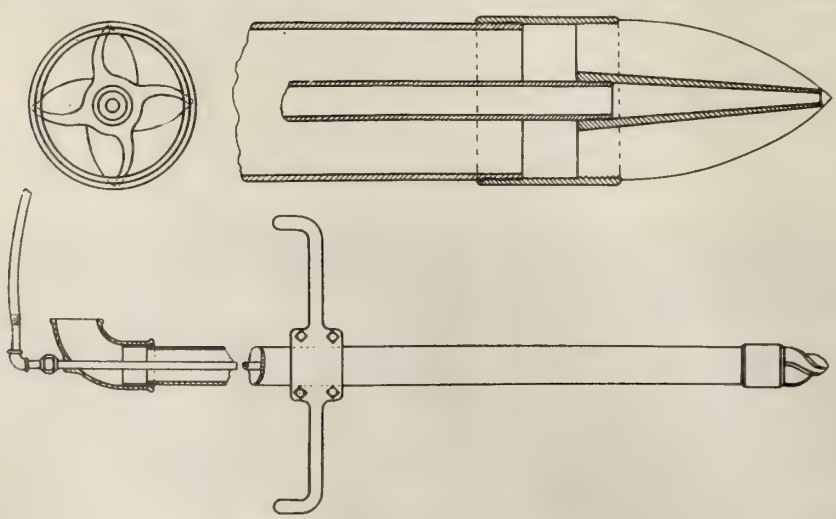
Showing how the light was arranged.

and so his only hope seemed to be in purchasing new machinery. Not having the necessary capital, he turned again to his present equipment and began speeding it up against advice. Today he is running all of the machines from two to two and a half times as fast as formerly—and his monthly repair bill has not increased one cent. A production in direct proportion was thus secured; and this has been particularly acceptable during the past year since German traps have flooded American markets.

Showing the model locomotive from two positions

EARTH BORING TOOL IN USE IN THE KLONDIKE IN 1898

By H. A. WILSON



A few days ago the writer had occasion to visit the Montreal office of the John Bertram & Sons Co., Ltd., and among several articles on an exhibition table on one side of the inner office was the tool about to be described. It appears that at the time of the rush to the Gold Fields in the Klondike in 1898, the miners with their crude tools could not make a great deal of progress through earth which was often frozen to a depth of fifteen feet. The late John Bertram had some friends engaged in mining under the crude conditions existing at that time in that region, and they asked him to devise some simple tool of a portable nature that would enable operations to be conducted throughout the winter.

The tool shown in the illustration shows what Mr. Bertram designed and built.

The outside body is made from ordinary 4 inch steam pipe. The small pipe in the centre of the large one is 1 inch steam pipe. The coupling, shown at the bottom of the apparatus, connects the pipe to a spiral four bladed earth augur made of cast iron. In the centre of the augur is cast a nozzle.

The one inch pipe screws into the nozzle. Steam is conveyed through a hose to the small pipe. This steam is ejected through the nozzle in the augur blades, into the earth. The steam thaws out the earth, then the auger is revolved by means of the handles shown in illustration. The thawed earth is then broken up as the auger is revolved and draws itself into the earth. The pressure of the steam blows the earth up the four inch pipe and ejects it through the large elbow at the top of the apparatus. As the hole gets deeper, additional lengths of pipe can be added. The handle clamp bolts being eased off and the handle clamped in a convenient position further up the pipe.

The tool was a splendid success. It was found that at certain steam pressures certain results could be obtained. Radiation losses were great and increased with the depth of the hole. Atmospheric conditions varied, so that actual results could not be tabulated for definite steam pressures. An expert operator could break up the frozen ground and have same ejected before it became too sticky.

WHERE IS MR. WATT'S?

There is a cheque at the office for John S. Watts, formerly of Box 553, New Glasgow. The post office notify us there is no one at this address. Can any reader tell us where Mr. Watts has moved to? If so, write direct to the editor.

DETERMINING THE COST

By W. F. SCHAPHORST

(Copyrighted By Author)

To figure the cost of your belt slip and creep you must first determine the percentage of slip and creep, which is a simple matter if conditions in the drive are such that the driven pulley can be operated for a while "without load." When no power is transmitted by a belt there is no slip or creep, of course. The driven pulley, then, will rotate as many times per minute as it is possible for it to rotate.

When the belt is transmitting full load, however, there is bound to be belt creep and possibly some slip, and the driven pulley will not rotate as rapidly as when "unloaded." The difference in r.p.m., then divided by the r.p.m. made "unloaded" multiplied by 100, gives the combined percentage of slip and creep.

For example, let us say that a given driven pulley runs 340 r.p.m. in an unloaded state. When the belt carries full load, though, it makes only 320 r.p.m. What is the combined percentage of slip and creep? Applying the above rule we get

340—320=20

20÷340=0.059

0.059 x 100=5.9 per cent. combined slip and creep.

Now, if this is a main belt drive it means that you are losing 5.9 per cent. of your coal pile through belt slip and creep. Thus if you spend $10,000 per year for coal you are losing

$10,000 x 5.9 per cent=$590.00 per year due entirely to slip and creep.

Why not apply some good belt treatment and save most of that? Spending a few cents to save several hundred dollars is surely a good investment. Why not take good care of your belts? Surely $590.00 per year is worth while.

MAKING A HOLLOW MILL CUT CLEAN

"Can you recommend a way of grinding hollow mill cutters so that they will cut a clean surface?" The question was asked by a reader of "Threads" recently and following is the answer given.

It is possible that when adjusting the tool the five screws on the face were not completely tightened. This would leave the cutters a little loose and cause the slight chattering which the samples show.

The evidence from samples submitted, is that faulty adjustment is the cause, although it may be that the cutters are somewhat too sharp. If this appears to be so, stoning the cutters very slightly on the cutting edge with a honing stone would relieve them slightly and give them better bearing.

At the end of the cut on the pieces sent is shown a burr which was thrown up ahead of the cutters. This would indicate that the hollow mill had been forced ahead just a trifle too fast on the stock. This could be proved by taking the cut a little more slowly and notice if the burr does not disappear.

PIPE WELDING

Continued from page 24

pressure without a break. In bending a group of 100, only one weld cracked in the bending, and that, being on the outside, was easily repaired.

In conclusion I will say it is well to bear in mind that pipe welding requires faithful attention on the part of the welder. All welders are not pipe welders. There is a need of much training to take care of the special conditions encountered. It is interesting work, and most good welders who take it up seem to like it as soon as they have been associated with it long enough to get familiar with the exacting requirements. This is another item to keep in mind as a part of the necessary research work by welding engineers to broaden the scope of practical uses of pipe welding.

Caoutchouc oil, if spread over iron and steel surfaces in a thin film with a piece of flannel and allowed to dry up will effectively prevent rust. If it should be desired to remove this protective covering it is only necessary to treat with caoutchouc oil again and wash after fifteen hours.

General Practice Adopted in Oil Refining

Selection of Refinery Site Very Important—Boiler Plant and Pumping Requirements—Details of Distillation Processes For Oils, Pitches and Asphalts—Fire Precautions

By C. D. DEAN, A.M.E.I.C.

AMONG all the great mass of technical literature, that devoted to petroleum refining is very meagre, partly on account of the great complexity in the physcial and chemical characteristics of crude oil and the products therefrom. In the past the technologists in the industry have been made from within and the extensions they made to the knowledge of the art were of a confidential nature until comparatively recent times, when the academically trained man with the scientific mind has found a place therein with the result that literature pertaining to petroleum has made its appearance, and no doubt from now on will increase in scope and volume.

The difficulty confronting anyone interested in the art and anxious to get a quantitative as differentiated from a qualitative knowledge of the industry is the preliminary data to which the usual engineering principles can be applied and in this paper by courtesy of Imperial Oil, some—at least—of this data will be given.

Selection of Refinery Site

In the selection of a refinery site, aside from the usual economic consideration such as markets, transportation, land values, labor and taxation the primary physical requirement is fresh water in comparatively large quantities for boiler and condensing purposes. Seaboard plants use sea water for condensing purposes if fresh water is scarce or difficult to obtain but one sea-board plant secures fresh water from a river 22 miles away.

Depending on the method of receiving crude and shipping finished products, as well as the variety of products to be manufactured, it is found that from 10 to 20 acres of land will be required per 1000 barrels of crude capacity daily. To minimize pumping heads, steam and electric power transmission losses, etc. the area should preferably be square and level, but as standard trackage is a necessity not only to handle current car movements, but also as storage for surplus empties, a rectangular area is usually selected—if available.

The total water requirements are usually found to lie between 1,000,000 and 1,500,000 imperial gallons per 1000 barrels of crude capacity daily, depending on the variety of manufacture, and ordinarily the pumping rate will be found to be quite uniform. For plants located on level ground the combined static and friction heads are rarely over 100 feet and during the past ten years the use of centrifugal pumps for this purpose, operating at speeds of 1500 to 2000 r. p. m. has increased, due to their well-known charactertistic of flexibility.

Aside from the requirements for mechanical power and heating, a great amount of steam is required for distillation and other uses in the process of refining and it is found that the steam requirements in our Canadian climate necessitate a boiler plant between 500 and 650 h. p. per 1000-35 I. G. barrels crude daily. The load is usually found to vary quite widely and overloads for sustained periods 25 per cent. above nominal rating are common. The water tube boiler is now coming into general use, but the nominal rating is figured 50 per cent. higher than the builders' rating and there is sufficient overload capacity left to take care of the variations encountered in refinery work.

Boiler Plant

Oil refining is a process carried on throughout the 24 hours each day and the boiler plant is the mainstay on which operation depends. The selection of the proper size of units for a boiler plant is sometimes rather difficult, but for refineries of up to 10,000 barrels of crude daily, 300 to 500 h. p. units are used. Above 10,000 barrels per day crude capacity, any large size of unit can be used, but it is generally felt that not more than 15 per cent. of the boiler capacity should be shut down at a time for repairs or cleaning.

As one-third of the total refinery fuel requirements which, if liquid fuel, would vary between 20 and 30 per cent. of the crude run daily, is consumed in the boiler plant, economizers and super-heaters, the former preferred, are a regular installation and it is pretty general the present day to install recording thermometers and water steam meters as well as CO_2 recorders, etc. in order to check and maintain efficiency and to ascertain, correctly, steam costs.

In certain locations fuel oil is used as refinery fuel, but it has so many advantages of an economic nature that makes it ideal as a fuel for ships and for heating purposes in cities, especially for offices and for public and private institutions, where transportation or cartage is a considerable item in fuel costs, that an effort is usually made to leave the fuel oil for these purposes. Generally speaking coal is favored as a refinery fuel and when it is used in boiler plants, especially in those of 1500 h. p. and up, stokers and power driven coal and ash handling apparatus are used, as in nearly every case they can be economically justified.

It is the general practice to locate the steam plant as near as possible to the centre of the refineries and carry the steam pipes supported on stanchions to the points where steam is used. In many of the processes, exhaust steam is as advantageous as the live steam and a network of exhaust lines, practically duplicating the live steam lines is installed. The steam pressures vary from 100 to 125 pounds gauge, while the exhaust line pressures are usually set at from 6 to 10 pounds gauge with an average of 8 pounds, and standard steel line pipe is used in both cases.

In general, it is found that the uses for exhaust steam are so varied and continuous that no waste from the exhaust lines occurs, and it is a rare thing to see the relief valves on them blowing. The current practice is to cover live steam lines with one inch of 85 per cent. magnesia, and one inch of hair felt with staggered joints and a final protective covering of roofing felt, while the exhaust lines have only a covering of one inch of 85 per cent. magnesia with roofing felt protection.

Under these conditions the radiation losses in live steam line are found to be approximately .248 b. t. u. per hour per square foot of external surface of pipe per degree difference in temperature between the steam and the outside air. The radiation losses from the exhaust lines are found to be approximately .463 b. t. u. per hour per square foot of external surface of pipe per degree of difference in temperature between the steam and the outside air. Taking the average boiler load throughout the year, it is found that the actual heat losses, from both live and exhaust lines, rarely exceed 5 per cent. of the generated steam.

The prices of coal have risen so much, compared with the prices of insulating materials, that a double jacket on exhaust lines would probably be financially justified. In designing live steam lines, the effort is made to keep the pressure drop for lines supplying large units of power to not more than 5 pounds.

Power Requirements

The requirements for mechanical power for pumping and other purposes, up to a few years ago, were all provided for directly by steam apparatus. In pumping, the duplex steam pump was used, while the throttling and occasionally the automatic cut off steam engine was depended on for general mechanical purposes, incident to the business. For some time a controversy has raged,

---

Author presented this information before the Toronto Branch of the Engineering Institute of Canada.

as to whether or not there was a loss in using power apparatus, which required large quantities of live steam when the exhaust could be used so conveniently in the process.

It has been found by more refined investigation that the losses incident to the blowing of exhaust lines have been practically eliminated by the use of more efficient steam using apparatus and besides a real saving in boiler fuel for the same refining capacity has resulted from the same cause, seemingly altogether due to the more efficient use of the heat units absorbed in the prime movers.

The substitution of the centrifugal pump for the old style steam pump has had the largest effect in determining the modern trend for mechanical power in refining work. It is the nearest approach to a duplex steam pump for reliability in refining operations where liquids of a viscosity comparable with water are to be handled and its use has introduced the electric motor. Profuse lighting is a necessity for oil refineries and with the advent of the electric motor, an electric power plant became standard apparatus in a well ordered plant.

It is usually found for lighting and all mechanical purposes, except pumping high viscosity oils, the electric power consumption for a plant on level ground will be approximately 1000 k w. hours per 1000 barrels of crude run. For plants built on sloping ground where comparatively high static pumping heads are encountered, it will be found that the electric power consumption will vary between 1500 and 1750 k. w. hours per 1000 barrels of crude run.

It is generally found that the maximum peak at the switch-board will be not more than 2-1½ times the 24 hour average, and the demand factor, figuring input to motors and watts per lamp, ranges around 40 per cent. but this latter figure must be accepted with reservations for obvious reasons. As far as the peak load ratio is concerned, intermittent services like loading and discharging steamers are not included because as they usually occur throughout a 24 hour period continuously, they simply add their input rating to the refinery peak. While it is true the refinery process is continuous, it is found that the peaks occur between 7 a. m. and 6 p. m.

The power characteristics usually selected are 440 volt, 3 phase, 60 cycles or 25 cycles, depending to some extent on the type of prime mover, and 440 volt apparatus was chosen primarily, because of the opinion that prevailed that this voltage would be safer for the operators, although the writer believes doubts on these points are confessed. The lighting voltage is all 120 and in the case of a small refinery is stepped down at the switch-board to save transformer costs. For large transmissions and comparatively large powers, where economically justified 2200 volts with step-up transformers are used and latterly for certain purposes 2200 volt apparatus is coming into use, although it is considered in its experimental stage, as far as oil refining work is concerned. Motor drives throughout are either the constant speed or variable speed induction motor, the latter being a rarity as it is only used to drive plunger displacement pumps.

POINTS TO REMEMBER

Fresh water, in comparatively large quantities, is necessary for condensing purposes.

From ten to twenty acres of land is required per thousand barrels of crude capacity daily.

A boiler plant of between 500 to 650 h.p. is necessary to supply steam for every 1,000-35 I.G. barrels of crude daily. The refining process is carried on throughout the 24 hours each day.

Exhaust steam is used extensively, so that there is practically no waste.

Power Factor

The power factor at the switch-board is found to be between .8 and .9 although on occasions the writer has seen certain plants go as low as .7, but it will be found that if the water pumps are carefully calculated and the oil pumps are designed to take the worst case, as far as head conditions are concerned, the motors will run close enough to full load capacity to give good power factor, especially if the generator capacity is flexible enough to have as near full load operation as possible. The transmission lines give a line loss of from 5 to 8 per cent. and trunk lines are generally liberally figured, because of the certainty of adding additional apparatus from time to time.

The type of prime mover used to drive the generators, is either steam engines or turbines, oil engines of the full Diesel or semi-diesel type and gas engines. The steam engine is favored for units up to 200 h. p. each, while for larger units than this the direct connect turbine or the belted oil engine is chosen with preference for the former unless the advantages of the latter are overwhelmingly in its favor.

The gas engine driven units are not adopted unless the plant is located contiguous to a large field yielding natural gas or unless the refinery produces large quantities of by-product gas and only then when fuel is high, giving the gas a high comparative value. As a rule the oil and gas engines are not flexible and cannot respond to overload without distress, and the manufacturers usually recommend that they be operated on continuous loads of 80 per cent. or less than their rating.

Crude Oil Reception

Crude oil in quantities is received by tank car, by pipe line and by tank ship, or any combination of these methods. The most favored means are by tank car or tank ship, because these means are independent of any field. As a rule, oil producing is a hazardous game and a pipe line usually requires a comparatively large capital expenditure. For short distances to the sea-board, a pipe line is preferred to tank cars, if the field warrants, while for long distances over land, the decision for pipe is a matter of considerable moment, and requires the exercise of judgment, based on long experience in the vagaries of oil production.

When crude is received by pipe line the tankage for receiving it is usually in two units, of sufficient capacity to hold a full week of pumping to guard against possible shut-downs of the line which frequently occur, enough to warrant the expenditure for this safe-guard. The two units are necessary to gauge receipts properly.

When receipts occur by tank cars, provision must be made for interruptions in railway service, as well as for the vagaries of train movements and transfers, so that it is customary to carry about a week's supply, although it is not unusual for the tank car situation itself to dictate the amount of storage necessary for crude because of fluctuations and peaks in the movement of finished products at certain periods of the year. When crude is received by tank ship the capacity of the largest ship, plus about fifteen days' supply must be provided for, due to the hazards of navigation and the difficulty of adhering to a pre-arranged schedule.

In the case of crude receipts by tank cars, pumps must be provided for unloading and these are usually made large enough to permit unloading and the redispatch of the empties within the standard 8 or 10 hours day between switchings if two per day can be arranged. While it may seem like an economic waste to dispatch cars empty, the fact is cars in crude service must be cleaned to carry refined oils and besides the cost of cleaning and the time lost to do this, is the uncertainty of load in the direction of the crude supply. Tank ships are equipped with steam pumps for discharging their cargoes, but the rate of discharge which should be high to minimize avoidable demurrage, is influenced by two factors; the capacity of the ship's boilers and the allowable pressure on the hose connecting the ship to the permanent lines on the dock. If the lines to the crude tankage are long or if the static head ashore is comparatively high, shore booster pumps are used of large enough capacity to accommodate the rate of discharge of the largest ship.

First Distillation

The first distillation of crude oil occurs in crude stills, which are operated either continuously in a battery or batch singly. Sometimes a combination of methods is used but the effort always is to get the most out of the crudes without using too much apparatus and the whole operation depends on the characteristics of the crudes—no two of which are alike.

In the first distillation the separations that are made are naphtha distillate, refined oil distillate, gas oil, lubricating distillate and fuel oil, as well as coke if distillation is carried to dryness. These distillates are usually run to gravities which have a range of boiling points, in which run considerable latitude is necessary but the aim is to approximate a degree of separation that reduces the necessity for subsequent distillation.

Continuous Method

The continuous method lends itself to an exchange of heat between the ingoing charge and the distilled vapour, as well as the residual bottoms and thereby gives an opportunity for fuel saving, but it is only used when running for fuel oil or in refining parlance topping, because it does not give good separation. In running for fuel oil, the aim is to prevent cracking and while distillation occurs at what is called "atmospheric pressure," the temperature rises and reaches the critical temperature for certain fractions. To eliminate this tendency in distillation, the temperature is reduced by introducing dry steam, which owes its efficacy to the law of partial pressures, but which, as before mentioned, causes the factions to overlap.

To get the most from crude in the sense of securing all the products with characteristics that are the most useful in industry, it seems to be necessary to distill to coke and do whatever cracking will naturally occur with a given crude at atmospheric distillation, which in reality is about ½ pound gauge.

In the skimming operation alone it is ordinarily found that from 8 to 35 cubic feet of fixed gas, under standard conditions, is produced per barrel of crude run, while in coking from 50 to 120 cubic feet of fixed gas is produced, and it is found that a relation exists between the gas and coke produced. There is a distilling loss which probably averages for paraffine base crudes around 5 per cent., but for asphaltic crudes goes as high as 15 per cent. As far as they will apply, considering the uncertain element from cracking, the specific heat of oil on the pound degree Fahrenheit basis is ½ b. t. u., while the latent heat ranges between 140 and 150 b. t. u. per pound for atmospheric distillation.

An effort is made to secure as good fractionation as possible in the first distillation by using reflux towers through which air circulates and knocks down the heavier fractions in the vapour stream. In designing these towers they are made as flexible as possible by some system of control of the air circulation and for certain crudes and certain rates of running, it is sometimes necessary to jacket the towers, at least, in part.

The modern still of 1000 barrels capacity, has two towers and 3 worms or condensing coils, or 3 towers and 4 worms and the design of worms is made altogether on the basis of a low rate of heat transference, about 1000 b. t. u. per square foot of surface per hour so as to provide great flexibility. Ordinarily the stills run either a 2 day or 3 day schedule, depending on the characteristics of the crude. The condensing water used is altogether based on the heat to be extracted from the oil and the rate of distillation, and for oils that have no viscosity the temperature is allowed to go as high as 120° to 140° F.

Cooling Certain Oils

For such oils as have viscosity at ordinary temperatures, as would retard flow in the worms and thereby increase the time schedule the practice is to cool these to a temperature that gives them low viscosity and this is done by taking the condenser water at 120° or 140° degrees F. from the light worms and using it to cool the contents of the heavier worms.

It will be appreciated that distilling to coke means very high temperature and the flue gases reach as high as 2000 F. towards the end of the run. As a general thing, the temperature of operations are all very high and as a result the labor needed to effect current repairs is as great as that needed in operations. All still equipment is designed to permit the making of repairs as cheaply as possible by arranging the fire sheets and brick work so as to minimize the amount of tearing down in order to affect the real repairs. For the same reason the worms are built of cast iron pipe installed so that any section can be removed and replaced without disturbing the other parts.

The draw-offs from the towers are arranged so that they can be sent back to the stills or on through the worm to the receiving-house and the run-backs to the stills are equipped with traps. Each worm runs to a look-box or turret in the receiving-house and the manifolds delivering to the receiving tanks are ordinarily placed in the ground floor of the buildings.

The gas is taken from the discharge end of the worms by a suction of about 2-½ inches of water, so as not to lift off any light vapours.

Treatment of Distillates

The finishing of the distillates is done by treating to remove unsaturated compounds, which give odor, color, etc., and subsequently distilling, but the order in which these are done depends on the product. In general, it may be said that treating is the first process in naphthas and refined oils and the last process in lubricating oils, but this is not necessarily so.

The treating of naphtha distillates is done either continuously or batch, and consists in bringing the distillate into intimate contact with commercial sulphuric acid of 66° Be. and after the re-actions have proceeded allow the sludge to settle out. The oil is then washed with water to remove all traces of the acid that can be removed by this means then settled again, after which it is treated with caustic soda or soda ash to neutralize the acid that still remains. The sludge is again settled out after which the oil is washed with water. In general, it is found that the quantity of water required in treating is equal to about 35 I. G. per barrel, while the quantities of acid vary between ½ and 12 pounds per barrel, and the quantity of soda solution is approximately 12 gallons per barrel. There is always a loss in treating, varying between ½ and 3 per cent.

From the treating plant the naphtha distillate is ready for finishing and is charged continuously to a steam still, where the gasoline is extracted by fractionation leaving a bottom or residue that is largely kerosene.

Steam stills, since they run continuously, are equipped with vapour heat exchangers, oil heat exchangers, oil coolers, water separators, etc., and in addition have over the still a large tower, where the ingoing charge trickles over stones through which the out-going vapours pass. The object of the tower is to knock down any kerosene fractions that may be leaving the still with the gasoline. The heating medium free live or exhaust steam is introduced into the still beneath the oil surface and it owes efficacy to the operation of the law of partial pressures, previously mentioned. The pressure in the still is not allowed to exceed about ½ pound gauge, if possible, but on occasions it may, and the still is, therefore, usually built, with spherical heads or is otherwise braced.

These stills are built usually of 1200 or 1500 barrels batch capacity and the running rate depends on the condensing surface in the worms which is, therefore, made ample. It is found that approximately 8 pounds of steam is required per gallon of gasoline or roughly 1 pound of steam per pound of gasoline overhead and the charge is fed at the rate of about 60 to 75 barrels per hour per still, requiring about 450 to 550 boiler horse power depending on the percentage taken overhead. On the condenser end of the vapour line means is provided for expanding the vapours before they enter the worm so as to take out any condensed steam and at the outlet end of the worm a trap is provided that takes out most of the water from the interior of the worm and discharges it to a sewer. It may be mentioned here that for this and all other stills, about a two inch thickness of magnesia blocks and a weather protection are used to minimize radiation losses.

In next issue we will take up the treatment of refined oil, proper storage, and other important points in the refining process.

The past year has been an active one in the building business in Hamilton. The annual report of the Building Inspectors' dept. shows the total value of all structures erected in Hamilton during 1921 at $4,649,450 as compared with a total of $4,340,220 for the previous year. In other words an increase of $299,230.

Review of Course of Business During 1921

By JAMES S. ALEXANDER
President National Bank of Commerce, New York

IN A REVIEW of the course of business during 1921 we look for an answer to the question as to what progress has been made in improving the conditions under which the peoples of the world must live and work. At no time in our history has this question been fraught with greater significance. Following are what appear to be the salient facts in the year's business history.

Anxieties, discouragements and great difficulties beset industry, commerce and finance during a large part of the year. Business throughout the world was groping for a way out of a maze of perplexities. While confidence was felt as to the ultimate outcome, it was impossible to plan beyond the pressing requirements of the moment.

Course of Business in 1921

A review of business developments in America during 1921 reveals with particular clearness the effects of community of interest with other nations upon our affairs. A consideration of these international bearings is necessary to a clear understanding of events in the year just closed and an intelligent outlook on what lies ahead.

The early weeks of 1921 were marked by a restricted movement of raw materials and manufactured goods, a continued rapid and irregular fall in prices, and a declining scale of industrial and commercial operations. Lower prices and lessened business reduced the pressure on bank resources despite the persisting burden of slow commercial credits. Wage reductions and unemployment reduced buying power, further curtailing business activity. Effective demand was further impaired by the failure of retail prices to decline commensurately with wholesale prices so that the net proceeds from the operations of farmers and other wholesale producers were not sufficient to cover a normal volume of purchases by them as retail consumers.

It was clearly evident that foreign conditions were exerting a particularly great influence in the situation. It is true that much of the weakness was caused by the inevitable reaction from domestic over-trading during the post-war boom. Nevertheless it was apparent that the present situation was essentially different from previous business crises. America's position in international trade had been greatly expanded and the world's impaired buying power proved insufficient to pay prices covering production costs of existing stocks or even to take new goods at reduced costs of production. The same was true of all other exporting countries, but, since America had the greatest export trade, its losses were commensurately large in the wave of cancellations of contracts, repudiations of shipments and defaults of commercial credits that swept over the world.

These world influences explain in a measure the halting progress and the disappointment of apparently justified hopes during the year under review. In the spring of 1921 there were some superficial signs of seeming improvement. Interest rates began to fall, reflecting better credit conditions, but reflecting also reduced business. The foreign exchanges grew stronger, but this reflected prospects of a satisfactory settlement of the German reparations, the shipment of gold to this country and the poor state of foreign trade in other countries, rather than any fundamental betterment in world conditions. There was a revival in the automobile industry, and a measurable improvement of sales in needed staple goods, but no general lift in activity.

World Price Situation

The basic business conditions continued to be subject to the weight on the markets of the world of accumulated stocks of merchandise. Prices continued downward. While price readjustment was a revival in the automobile industry the irregularity of the movement produced a difficult world situation not only in respect to different classes of prices, but also as to price levels between nations, adding to the difficulty of international trade and to the instability of the foreign exchanges. A renewal of reactionary movements and increased pessimism characterized American business at the middle of the year. Slackening industry here forced labor to accept further wage reductions.

The dullness and pessimism that characterized the summer months were followed by a revival of activity in the closing months of the year, largely seasonal and mixed in net results, but more substantial in character than that in the spring. Favorable crop conditions resulted in large yields of grain. The proceeds of the crops provided a measure of relief to the rural banking situation through a moderate liquidation of loans. But the full stimulus of what, by itself was a successful agricultural season, was not felt in the retail markets and related industries because of high retail prices relative to the extensively deflated prices the farmers received.

Sustained activity in the investment market occurred the latter part of the year. This reflected completion of the liquidation of security holdings brought about by business reaction, the accumulation of idle funds seeking employment as a result of reduced business demands, and particularly it reflected a levelling process resulting from declining interest rates, which made it increasingly profitable to buy securities at prevailing low prices and consequent high yields. The movement resulted in extensive absorption of United States Government issues, carrying them up toward par, and probably constituting their ultimate distribution on a permanent investment basis.

An important development in the closing weeks of the year was the vigorous upward movement in leading foreign currencies, sterling going to 4.24, the highest point reached since October, 1919. Sales here during the year of securities from foreign sources, net shipments of about $700,000,000 in gold to America and large speculative dealings in foreign currencies contributed to the improved position of several of the foreign exchanges. Barring broader elements of strength back of these factors their ultimate effect might well be further weakness of the foreign situation. This is particularly true in respect to the further distortion of the world's gold supply that occurred. We may, however, feel confident that accumulating elements of betterment in world economic conditions were indicated by progress in solving major problems of unsettled national relations as foreshadowed by the promise of favorable results from conferences on the Irish question, on the German reparations and on the limitation of armanents and Pacific problems.

Strong Condition of Banking System

The year's end found our banking system in a notably strong position. Cognizance must be taken of the fact that there remains a considerable residue of non-liquid bank loans, whose settlement constitutes a particularly difficult phase of deflation because of especially hard conditions in respect to the businesses and the merchandise markets involved. But the burden of retarded credits has been very materially lightened. The total volume of commercial credit has contracted in keeping with lessened requirements due to lower prices, liquidated transactions and reduced activity.

The position in respect to gold reserves is unprecedented. In fact, due to the flood of the metal from abroad, the nation has an embarrassment of riches in this respect, involving the conceivable possibility of cheap money and

credit inflation. But serious results need not be feared if the requirements of sound business rather than the physical volume of gold be made the essential criterion of credit expansion. Fortunately the enlightened policies and skilled management of the Federal reserve system have firmly established it in the confidence of the nation's practical bankers as an instrumentality with which they can co-operate effectively in conducting commercial banking as a whole on the common sense lines which this situation requires.

Keener Competition

In the industrial and commercial situation, many elements of weakness have been eliminated through adjustments to new conditions accomplished by the stronger concerns and through the reduction in the number of weaker and uneconomic business units brought into being during the boom period. There has been a return of keener competitive conditions, and an increase in both personal and corporate efficiency and economy. Potential demand exists for goods really desired or needed, coupled with a spirit of thrift that in the long run creates more staple and desirable markets. The period of collapsing price movements, yet in progress at the opening of 1921, is generally over.

Against the general factors must be set off certain unfavorable conditions still inhering in the total situation. Particular emphasis must be placed upon the adverse aspects remaining in the element of prices due to the lack of alignment as between consumers' and producers' prices and also as to price level between nations, and the accumulation throughout the world of excessive supplies of many commodities whose distribution was halted by world-wide impairment of buying power. While probably no general state of overproduction exists, and while excess stocks habe been lessened, further substantial reductions or better distribution must occur before price equilibrium and market stability can be assured. Further reduction of production costs is necessary. This is rendered difficult by high overhead charges from expensive, over-built or idle plant equipment, by too high railroad rates and by the burden of government taxes.

Necessary Cost Adjustments

It is beyond argument that the nation's heavy war obligations must be met, and sufficient taxes must be levied to meet them. But business should assert its rights to unceasing economy in public expenditure and to further adjustments of taxation to reduce to a minimum its hampering effect on productive effort. Railroad transportation costs must be reduced to a more economic relationship with industry and commerce.

Although this involves wages and efficiency, the interests of labor in these readjustments are absolutely identical with the interests of business and of the public in that they will make for stability of employment and lower the costs of living.

The net situation presented by these various factors warrants confidence. No great difficulties appear in general financial aspects in the domestic field at the end of the year comparable to the inflation, no-liquidity and widespread insecurity of credit prevailing at the opening. Fears of credit stringency have been replaced by a justified confidence that funds for desirable business will be available at reasonable rates. The chief drag on business now is from market, not financial conditions. It can be lightened only by the processes which will restore equilibrium between supply and demand. Because this is a world-wide matter, confidence in America's business future must be tempered by conservatism in making business plans. If we were a wholly self-contained nation and consumed all that we produced the balance of favorable over unfavorable factors would be our warrant for looking ahead with unqualified confidence. Related as we are to the rest of the world the practical outcome will be largely affected by what happens in other nations.

The foregonig facts emphasize with particular force the imperative character of the conservatism and economy which the times demand. In personal matters, in corporate management, in government administration and in international conferences they must dominate the conduct of affairs and constitute the chief end sought. The world must produce more than it consumes, if resources are to be found for strengthening the weakened structure of industry and commerce. It must employ its energies efficiently if the structure is to be staunch and if progress is to keep pace with human desires. There is no magic to wipe out the effects of the great war. That can be done only by hard work, efficiency and economy. These have been the great source of safety in the year just closed and are required for success in the year that lies ahead.

HELPFUL FIRE PREVENTION MEASURES

Lack of precaution is often the cause of a disastrous fire. In the interest of fire prevention due attention should be paid to the following points, each of which is an acknowledged contributory cause of many fires:

Keep buildings clear of litter and rubbish; never allow accumulations at the bottom of lift wells, nor permit rubbish to stand by stairs, in corridors or near stoves; place all waste paper, rubbish, etc., in metal receptacles, and have them emptied regularly.

Keep roofs and gutterings free from paper, dry leaves, etc., as these may easily be ignited by sparks and burn for some time without being noticed.

Avoid swinging gas brackets which may be pushed against curtains or woodwork.

Use only fixed metal tubing for gas stoves. Rubber connections and flexible metal tubing (which is rubber lined), may fuse if the flame "fires back." If this remains unnoticed, the connection burns away and the gas flame pours out from the tube, firing everything within reach.

Place all gas heaters and stoves on metal stands.

Never permit electric wires to remain uncased or to be left severed with the ends unbutted.

Disconnect wall plugs from all electric radiators when not in use.

Keep floors of all oil stores as free from oil as possible.

Have all oily waste put into metal bins provided with lids.

Never permit turpentine, paraffin, and similar highly inflammable liquids to remain in "drip" tins.

Never allow smoking in the vicinity of highly inflammable substances or packing materials.

Never allow wooden boxes to be used as coal boxes. They are liable to be used for ashes raked from the fire and these may easily break into flame.

Never rake out fires before leaving for the night. Use a guard or dampen down if there is too much fire.

Forbid the throwing down of lighted matches or cigarette ends, either on the floor or out of the windows.

PORTABLE OIL FUEL BURNER

Mr. A. H. Wilkie, 78 Duke Street, Liverpool, England, has developed an oil fuel burner of the portable type that is especially designed to be of use in foundry work. Two types are made, one operating by means of compressed air, the other by a hand air pump. The compressed air type has the advantage of instantaneous starting. There is no preheating necessary, and as there is no coil, there is no choking through carbonization. Any kind of oil fuel can be used. The burner is said to be particularly economical when used to dry floor moulds. The use of the burner to dry steel moulds is also said to have shown remarkable results. The fuel saving is from 25 per cent. to 50 per cent., and in two hours a mould can be dried that would require twenty-four hours with a coke fire, according to the maker.

For lighting up a cupola it is also used to advantage. A 5 inch steel pipe is placed in the bottom of the cupola and the coke placed on the hearth. The pipe is withdrawn preferably through the rear opening if one is provided on the cupola. Thus an arch of coke is formed and the burner flame introduced here. The result is the first iron down is clean and hot. There are no ashes in the bottom of the cupola, and no fear of a back draught. The burner is used to preheat castings for burning or welding drying ladles, and heating steel ladles prior to taking the metal from the convertor or electric furnace. This method of preheating ladles is clean and can be continued up till the moment the ladle is required, thus avoiding the possibility of chilling.

New Things in Shop Equipment

ADJUSTABLE RATCHET WRENCH

The Simplex Iron & Tool Co., Toronto, Canada, has developed and marketed a new type of adjustable ratchet wrench which is said to do away with the use of numerous spanners. The makers claim it is adjustable to any nut within its range, that it is fool proof, that the nut or rack will not strip, that ratchet locks in any of nine positions through an arc of 180 degrees, and that no corner is to awkward for its use. The wrench is made of drop forged steel and is especially hardened throughout. Three sizes are carried, 6 in., 8 in. and 12 inch.

DETACHABLE COUPLING

A ready detachable, leak-proof, metal coupling, known by the name of "Knorr" has recently been placed on the market by the Barlow Mfg. Co., New York. The coupling is suitable for hose used in pneumatic or hydraulic lines. It has shown its ability to withstand pressures up to 450 pounds per square inch. Three or more arms closely embrace the end of the hose of any given outside diameter, these arms being held in place by a steel ring. The grip of the arms on the hose is actuated through a wedge or spreader nut, threaded on the shank of the coupling, which forces out the arms at the hose end of the coupling. This lever action enables the user to exert an easily adjusted pressure upon the hose when attaching to a piece of hose and to detach quickly by revolving the spreader nut several times. Slight variations in the thickness of the hose do not interfere with the action of the coupling

ELECTRIC PLANER CONTROL

The General Electric Co., Schenectady, N. Y., has recently placed on the market an apparatus for preventing the tables of electrically controlled planers from over-travelling. The apparatus makes use of the dynamic system of braking for stopping the table, as it is claimed it will prevent over-travel either on the reversal of the planer or because of the failure of the voltage. A selective-resistance contractor is used to adjust the value of a dynamic brake resistance for either direction of rotation and can be adjusted independently. It is possible to set the braking effect at 200 per cent. instead of 100 per cent. of full load thus greatly reducing any tendency to overtravel.

It is claimed that this method of control will give absolute dependability as well as ease and certainty and also lends itself to a wide application. It is also a great time-saver. Should the contacts or tips become welded together because of severe service conditions the planer will stop, but it will not overrun its set limits. Should a failure in voltage occur, overtravel is eliminated because of the fact that the motor is always connected on the dynamic brake. It is possible to "jog" the table using either a master switch or a push-button station. The selective-resistance contractor enables the machine to operate on jobs allowing but small tool clearance. It also is possible to work on jobs where the duty varies from no load to full load and where cuts are made to the extreme end of the travel.

GRINDING AND SEWING MACHINE

The Wonder Grinder Co., Erie, Pa., has recently placed on the market a spindle type grinding and sanding machine, which was designed primarily for internal circular grinding in both wood and metal. The work-holding table of the machine is circular, and is provided with two bearings through the medium of which it can be tilted 45 degrees on either side. The table automatically locks in position at right angles to the spindle. However, it may be set and locked in any desired position within its range, by means of a knob located in front of a protractor scale.

The spindle or roll carrying the abrasive is mounted on a vertical shaft and driven directly from a ¼ h.p. motor which is mounted in the base of the machine. The motor is accessible and can be easily disconnected and removed. The spindle revolves at a speed of 1725 r.p.m. The top bearing is adjustable to compensate for wear. Lubrication is through the medium of a grease cup. The spindles are 9 inches in length, and are provided in diameters of 1¼, 2¾ and 4½ inches. The oscillation of the spindle is ⅞ of an inch. Various types of motors can be supplied either direct current, or alternating current to operate on 25, 40, or 60 cycles. The controlling switch is conveniently located on the column. The diameter of the table is 20½ inches and the height above the floor is 37 inches.

GASOLENE-KEROSENE BLOW TORCH

The Turner Brass Works, Sycamore, Ill., have placed on the market a blow torch of new design, which will use either gasolene or kerosene. The shut-off valve in this torch is placed below the orifice. This idea prevents enlarging of the orifice through shutting off tightly when hot by forcing the point of the needle in, or through fuel corroding the needle point when the torch is cool. All gases are permitted to escape through an adjusting needle and any desired size of flame can be obtained without destroying the orifice. Regardless of the flame adjustment, a cone shaped tube on the burner siphons the correct amount of air. The feed tube is located on the outside of the tank thus preventing any possibility of heating the fuel in the tank to a degree that would cause any danger of an explosion from gas pressure. The leather in the plunger of the air pump is loose in the cylinder, thus decreasing wear, and allowing air to pass freely on the upward stroke. On the downward stroke the leather flares out and forces a large amount of air into the tank.

LARGE DIE SINKING MACHINE

A new die sinking machine incorporating unique features particularly adopting it to handle large dies, has been placed on the market by the Pratt & Whitney Co., of Hartford, Conn. By means of "Bayrer's Compensating Arms," a die weighing four tons may be suspended by elevating screws and readily placed in position on the table and easily swiveled, tilted or turned on edge by the operator. The hand feeds are thereby rendered sensitive to light cuts and the die may be fed over to extreme limits for cutting gates without the slightest cramp.

The compensating arms can be folded back and latched against the sides of the column. The hinge shafts for the arms with the massive ears, are attached to the column. The arms are carried on roller bearings supplemented by ball bearings; they are therefore, very sensitive to any movement imposed on the die. Both of the outer carrying arms are provided with balance beams and adjustable weights by which the load of the die can be approximately balanced and relieved from the table. Crabs attached to the ends of die provide trunnions by which the die is supported and on these trunnions it may be readily tipped on its side for edger cuts. When the die is being tipped on its side the table is dropped clear of the die, the arms sustaining the entire load.

The machine is of the knee type permitting proper elevation of the dies of various thicknesses to bring the cut to a convenient level for the operator. To this end the range of the knee travel is kept exceptionally low down and platforms are unnecessary. The cutter spindle is mounted in a counterweighted vertical head provided with hand feed with a graduated dial. A rapid traverse for the quick adjustment of the head is provided. Power to the cutter spindle is transmitted through a quarter-turn belt from the gear box in the rear of the machine. All changes of speeds and feeds are made by levers in front of the machine convenient for the operator.

Hand and power feed are provided for both the longitudinal and cross feed of

the table. In addition a rapid power movement is provided for all movements of the table including elevating and depressing. The mechanism driving the power movements operates through friction to prevent injury to parts in case of over-running.

A cherrying attachment is readily applied to the cutter head; drive is effected through gearing to the nose of the cutter spindle. When not in use the cherrying attachment is swung back out of the way and does not interfere with the use of the machine. The machine is equipped for either a constant speed drive direct from a line shaft or from a motor mounted on the machine. It is also made with and without the die-carrying arms.

Dimensions of Machine

Table top dimensions ..	22 in. x 48 in.
Table longitudinal feed	48 in.
Table cross feed	17 in.
Table vertical feed	15 in.
Cutter head vertical feed	12 in.
Spindle speeds (12) ..	27 to 79° r.p.m.
Table power feeds (9)	9/16 to 10 in. m.
Table rapid traverse	42 in. per m.
Floor space parallel to table	10 ft.
Floor space right angle to table,	10 ft.
Height of machine	9 ft.
Weight, approximately	16,000 lbs.

GRINDING, DRILLING AND TURNING MACHINE

The Ex-Cell-O Tool and Mfg. Company of Detroit, Mich., have recently developed and placed on the market a combiation machine which is capable of handling grinding, drilling and turning operations. The new tool is essentially a bench machine, the frame consisting of a central circular column symmetrical throughout, the upper portion being turned. A large filleted flange at the bottom serves as a foot. The machine handles a variety of work, among which is the grinding of valve reseating tools and valve cages, turning commutators and gears, sharpening milling cutters, drilling and regrooving of pistons, and the milling of key-ways. The machine is equipped with a spindle at the top of column, and this spindle carries its own ¼ h.p. motor whch is connected by a belt. The spindle can be inclined at any angle, and speed changes are provided through the changing of pulleys. Reciprocating motion can be imparted to the spindle for grinding and milling operations.

The lower spindle is mounted on a head which travels on a guide rail, which is in turn clamped to the column. This can also be swiveled to any angle. It can be equipped with a 6" face plate, or a 4" scroll chuck, and is operated by means of a hand wheel. It can also be power driven by the electric motor, through the medium of a "V" belt which operates on a pulley on the shaft extension of the motor and on the hand wheel that has a V groove turned in its large diameter. The upper spindle is equipped with ball bearings throughout, and the work spindle has a straight bearing which extends its full length, and it has a ½ in. 45 degree angle-thrust bearing. Both internal and external grinding operations can be taken care of. The lower spindle head has a travel of 7 inches and a vertical movement of 8¾ inches. The machine has an over-all height of 24 inches and weighs about 135 pounds.

DIAL INDICATOR

The Atlas Indicator Works, Chicago, Ill., have recently placed on the market two types of Dial Indicators, known to the trade as the "Atlas Junior" and the "Atlas Universal." These instruments are designed to be of use to die makers, inspectors and tool makers, or in any operation wherein delicate measuring is essential. A pamphlet describing various applications of these indicators has been prepared. The outstanding principle incorporated in the design is that the indications, or readings, are made from a dial, and not read from the ordinary sector. Attachments are provided in the regular equipment, which permit the instrument to be used in a multitude of ways. From one side of the dial casing a small rod extends to which is attached a clamp. In a lug of the clamp there is a small hole of suitable size to permit the pointer or scriber of a surface gauge to be inserted. A small thumbscrew tightens down on the scriber after it has been inserted. In using the indicator in this way accuracy and speed are obtained as well as deriving the added advantage of direct reading.

Several cuts in the pamphlet show numerous applications. The instrument is equipped with a goose-neck rod extension which attaches to the frame of the dia.. This rod can be clamped in a tool post to gauge the eccentricity of a revolving piece in a lathe. Similarly the indicator can be used on vertical milling machine horizontal boring machines, etc. There are many other applications such as one which enables the plunger to extend at right angles to the face, as well as the ordinary extension of the plunger, parallel to the face of the dial. The accessory attachments are universal in range.

Another important feature is that it is capable of adjustment. That is to say, if the dial registered, say .003 in. eccentricity or variation, and for the purpose of getting relative measurements or indications on subsequent readings, the reading could be made zero and from then on, all readings would be made relative to that zero point. The indicator reads by thousandths of an inch to .130 inches, and is provided with an extra tip to be used on uneven surfaces. This tip lessens vibration and gives more accurate measurements on these rough surfaces. The machine is light in weight, nickel plated and comes complete with all attachments.

The Junior indicater, also illustrated on a leaflet, has been produced to meet the need of those who require a small, light, but highly accurate tool. The net weight is ¾ of an ounce. The circular dial is 1 inch in diameter, and the over-all length is 2½ inches. The instrument is very sensitive and durable, and the housing is made of machine steel, case hardened. The important working parts are made of high grade tool steel hardened and polished. The housing is mounted in a swivel clamp and the dial is graduated to read .001 of an inch, at an angle of 90 degrees, but the contact point can be set in any desired position so that the reading may be magnified or diminished to facilitate inspecting operations. This latter instrument is also capable of adjustment.

STAYBOLT ATTACHMENT

The Acme Machine Tool Co., Cincinati, Ohio, has placed on the market some improved staybolt equipment which has been designed for use on their flat turret lathes. An overhanging plate is bolted to the turret and two die-heads are used. The equipment has several special features and it is claimed by the manufacturers that it will produce a staybolt which is accurately made as to concentricity and lead. It is very essential to have both die-heads cutting the thread simultaneously, so that the leads will correspond exactly with the taps. The rear die head is made adjustable so that any length of bolt within a wide range can be handled.

When using bar stock the sequence of operations are as follows: The roller back rest multiple turner is used to turn the thread diameter. While this is being turned the recessing slide is use to complete the relief. Both die-heads are operated simultaneously to cut the thread. The dies are set from a master or staybolt tap to insure the two threaded portions to be as one continuous lead. The last operation is to cut the staybolt from the bar with cut-off tool held in the slide tool. When using forgings forged to the correct thread and recess diameters, and length where the continuous lead is desired the two die-heads are used in the same manner as for bar stock. On the 2¼ in. x 26 in. Acme machine, 1¼ in. diameter die-heads are use, an the maximum length of staybolt that can be machined is 25 in. On the 3¼ in. x 36 in. machine, 1½ in. dia. heads are used and staybolts up to 33 in. can be handled. On the No. 3 Universal machine 1½ in. die-heads are also used, but a length of staybolt of 36 in. can be machined.

WRITING ON STEEL

Writing on steel can be effected by first cleaning the metal with oil, wax over it. The writing should then be done on the beeswax with any convenient sharp tool and the marks painted with a small brush dipped in a liquid composed of one ounce of nitric acid and one-sixth of an ounce of muriatic acid. The lines, filled with this corrosive acid, should remain for five minutes, after which the metal is dipped in water, then cleaned and dried.

There Is Need For Haste

ARE WE going to have a New Machinery Hall at the Toronto Exhibition grounds this year? Canadian manufacturers are vitally interested in the proposed structure, and have shown their interest in no uncertain manner. Up to the present time guarantees have been given for three times the space occupied by the now obsolete building which was used again last year.

The gentlemen appointed to secure these space guarantees have turned over their report to the exhibition committee, who will consider it some time within the next few days. It is to be hoped that a decision will be arrived at which will mean an immediate start on this building, for it is badly needed.

A new machinery hall would be an added feature to the exhibition and if placed in a more suitable location, would attract many visitors, who at the present time do not know a machinery exhibit exists. The city authorities have the final say regarding the erection of the new hall, and we cannot too strongly urge them to give the matter their immediate endorsation in order that erection can commence at once. If the building is to be used during the Fall of 1922, it means that all concerned will have to work rapidly and in absolute harmony.

Reducing Handling Costs

ON EVERY hand, plant owners are looking for ways and means of reducing production costs. In some cases wages have been reduced, but this is a very small item when compared with other efficiency leaks which are often allowed to pass unnoticed. Take for example the handling cost.

Sometimes, an otherwise capable superintendent, fails to grasp the importance of proper handling facilities. Lest this may seem a rash statement, here is a case in point. In a large agricultural implement plant a certain part had been drilled in a standard manner for several years. Production engineers felt that the method employed was about as simple and efficient as possible, yet were not satisfied with the drilling cost. It was the operator of the machine, who, unconsciously, solved the difficulty.

"If I didn't have to dig into that truck for the pieces all the time," he grumbled, "I could get the parts out quicker." Like a flash, the engineer saw the solution. A chute was made which fed the parts by gravity to the workman. Production soared, and a piece of tin, not even a roller conveyor, accomplished the whole thing. Simple—yet its very simplicity allowed the engineer to miss the point until it was called to his attention.

On another page of this issue appears an article on gravity roller conveyors. Many plants have found this system to reduce handling costs considerably, but the problem does not end here, for cranes, trucks, and all other transportation aids enter into the handling problem.

Have you ever walked through a plant which was well supplied with cranes in the center portion, but poorly equipped on either side? Then there is that type of factory which refuses to purchase new trucks, with the result that their handling costs soar, whereas by buying a few modern trucks, the saving effected in handling would soon pay for the new equipment.

When considering the purchase of handling facilities do not look at the initial expense only. This is a small item when compared with the ultimate saving. It's like putting money into a good investment, for not only have you the article itself, but the resultant benefits and saving. Even though times are such that expenses must be curtailed to a minimum, do not adopt a penny wise, pound foolish policy, but where you see the chance of eventual saving, do not hesitate to secure the necessary handling equipment.

No Room For Pessimists

IF THERE was ever a time when men required common sense optimism, it is now. This is no time to preach blue ruin, and apart from that, there is no reason to feel that things are going to the tarnation bow-wows, for they're not.

Have you ever met that type of man who keeps on kicking about the inefficiency of the government, the possibilities of strikes, and displays a disgust of the world generally? Of course, you have, for unfortunately, like the poor, they will always be with us. There should be some form of punishment meted out to this type of individual. In fact a good plan would be to start a colony of such croakers and they would soon tire of their own twaddle.

We are living in a great country, and we are right in the midst of one of the greatest periods for usefulness and common sense the world has ever seen. We all need to put our shoulder to the wheel of industry, for only by concerted effort can we get out of the mire of stagnation.

The world in general has passed through a churning process during the last few years, and we cannot expect things to settle all at once. It will take time, and while this evolution is taking place, it will pay us to practice sane optimism and clean thinking. The next time you meet a pessimist, and he starts grumbling, ask him what's wrong with Canada. If he answers your question intelligently, then we miss our guess.

Latest News From Various Markets

A Better Feeling Exists On Some Markets

Orders Being Closed Are Small in Volume But Large in Number On Good-Sized Business Concessions Made—Small Tools And Supplies Active—Machine Tools Still Dull

THERE is a decided improvement in the local market this week. Steel merchants are finding business better than they expected, and the total of January should show up favorably. No particular line is being sought after. Orders are for small quantities, but the number closed, makes up for the size of the order.

Small tools and supplies in both the Toronto and Montreal fields, are in good demand. High speed drills have dropped ten per cent on the local market. This is expected to stimulate the demand.

Scrap metals are weak, cast iron being the only one to hold its own. Other metals such as lake copper, tin, and antimony, have tapered off slightly in price.

Machine tools are still dull. Enquiries continue to come in, but the largest percentage do not materialize into orders. No improvement is looked for at present, and until factories open up, no special demand is expected.

Pittsburgh reports a highly competitive market. Every mill feels that they must secure all possible business as there is not enough to go around. Concessions in price are more frequent, especially on an order of any decent proportion.

Sheets are firm, with wire products next in order. No material decline in steel prices is looked for, as it is thought the market holds little room for further drop. The mills, while eager for business are not slashing prices.

Manufactured steel prices have dropped somewhat during the past few weeks, but this move was expected as this class of goods did not decline as rapidly as the hot rolled milled products from which they are made. Rivets, chain, and bolts are included in the reduced lines.

KEEN COMPETITION ON STEEL MARKET; MANUFACTURED STEEL ARTICLES DROP

PITTSBURGH, January 25th.—Demand for steel is increasing in the new year but at a slower rate than was expected in most quarters. The result is a highly competitive market. In the trade generally, remark is being made as to the keenness of competition. The attitude of the mills is plain. Each feels that there is so little business going that it must get every order it possibly can. There seems to be a fear on the part of the individual sellers that if they once get out of the market they will never get in again. There is no thought of any mill, except very small ones, closing and waiting a few months for conditions to get better. This situation is of course due to the very large steel producing capacity existing. If one-third of the mills should withdraw entirely, the remaining two-thirds could make more steel than was required before the war when the country was very busy and consumers of steel felt they had all the business they wanted. The point must not be overlooked that a volume of business that would satisfy consumers to a certain extent would not satisfy producers to the same extent.

Concessions More Frequent

A very decided change has come over the situation as to finished steel prices in the past ten days, one that is a matter of common remark, but the change is not that the market is quotable on a lower basis. As a matter of fact bars, shapes, plates, hoops, wire, nails, sheets, pipe and tin plate are every one quotable, in the open market, at the same figures as for a month past. Yet on the whole the market is lower. The change is that concessions from regular prices that were formerly being made on large lots have now exteneded to moderate sized lots. In some commodities the concessions are so frequent that the regular prices apply only on orders up to say 100 tons. A 250-ton order would draw a concession from the regular price when two or three weeks ago it would require an order for say 1500 tons to cause the same result.

The regular market remains quotable as follows: Bars, shapes and plates, 1.50c; hoops, 2.00c; standard steel pipe, 71 per cent basing discount; plain wire, 2.25c; galvanized wire, 2.75c; wire nails, $2.50; blue annealed sheets, 2.25c; black sheets, 3.00c; galvanized sheets, 4.00c; tin plate, $4.75. Of all these, black and galvanized sheets are easily the firmest.

So far as is known, no buyer has been able to budge any mill from the quotations shown, and in blue annealed sheets the market is probably firm also. Blue annealed sheets are misrepresented in some quarters by references being made to sales by plate mills. Such sales are made on the plate mill basis, and the price is necessarily lower than the blue annealed basis, but the material is not blue annealed sheets. The thickness may be the same but the finish is different and the material is practically certain to be less true to gauge. In the heavier gauges some buyers are satisfied with the plate material, when they can save money by buying it.

Wire products probably come next to sheets in point of firmness. There are some price irregularities, but perhaps these are simply departures from Pittsburgh basing, not representing weakness as to deliveries in most sections of the country. In tin plate, concessions are given on large orders, just as was the regular thing before the war. In pipe, the irregularity is chiefly that the independents are going a trifle under the prices of the National Tube Company, as they usually do.

Rate of Production

Mills had so little forward business on books that the decrease in consumption that comes with winter, and the lull that occurs in buying just before the annual inventory date, promptly made an impression on the rate of production. In most years the mills have enough momentum to carry them over the turn of the year. While a close estimate cannot be made, it seems to be a fair guess that at this writing steel ingots are being produced at the rate of 18,000,000 tons a year, against average rates of 20,000,000 tons in December and 23,000,000 tons in October and November.

As has been the case most of the time for over a year, the United States Steel Corporation is operating at a considerably higher percentage of capacity than are independents. One estimate is that at present the corporation is running at 40 per cent. and the independents at 30 per cent. The corporation has an advantage on account of its holding prices down in 1920 when the independents advanced, and allocating its output fairly to its various customers. The corporation has no price advantage over the independents now. As a matter of fact, since February 1, 1921, the corporation

has, on an average, received slightly higher prices than the independents.

Market Prospects

There is no likelihood of any material decline in steel prices. Averaged according to the total tonnage being sold, concessions from regular prices only run say $1 or $2 a ton, and it is noticed that very large orders do not draw materially lower quotations than a few weeks ago. The market has little room to decline farther, except in a few lines, nails no doubt being one of these. Prices are approximately at cost of production and in the case of many mills they are at less than cost of production. The mills are competing eagerly for business but they are not slashing prices. If a much larger operation were attainable mills might go lower, because then they could get down their costs.

Manufactured Steel

For the past year it has been noticeable that various manufactured steel articles, fine nuts and bolts, rivets, chain, cold finished steel bars, spikes, cold rolled strip, etc., did not decline as rapidly as the hot rolled mill products from which they are made. These lines in general have been showing a declining tendency lately. Rivets, formerly 2.25c for structural and 2.35c for boiler, can now be bought at 2.20c and 2.30c respectively, perhaps in the case of large orders at 2.15c and 2.25c. Chain recently declined from 5.90c to 5.50c, in the base price. Cold finished steel bars, recently steady at 2.00c, can be had at 1.90c possibly even in carload lots. In the past few days nuts and bolts have been shaded particularly. Large machine bolts which ten days ago were steady at 70 and 10, have been obtainable in the past few days without difficulty and 70, 10 and 10.

Pig Iron and Coke

The pig iron market remains very dull, quotations being still $19.50 for Bessemer, $18.25 for basic and $19.50 for foundry, f.o.b. valley furnaces. Connellsville coke for spot shipment is easier. Furnace coke can be picked up at $2.75. Foundry in ordinary grades still sells at $3.75 but the $4.50 price on fancy brands has disappeared, $4.25 being a price that would command almost any brand. Some coke is offered at $3.50 but it does not appear to be standard.

POINTS IN WEEK'S MARKETING NOTES

Keen competition exists on the steel market. The mills feel there is so little business to be secured, that they must get every order they possibly can.

A decided change has come over finished steel prices. Concessions, which were formerly made on large lots are now extended to moderate sized orders. In fact in some cases the regular prices apply only on orders up to say 100 tons. Above this figure, a better price would be given.

No material decline in steel prices is looked for as it is felt that the market has little room to drop further. There may be a few exceptional lines which will drop slightly, but generally speaking, present prices are very close to the cost of production.

Manufactured steel prices show a tendency to sag however, for rivets, chains, cold finished steel bars, and all sorts of bolts have dropped in price during the last week or two.

The pig iron market remains very dull, while coke is somewhat easier.

Montreal reports little change on the market. The only department which has picked up at all is the small tool and supply business. This has improved considerably, and farmers are purchasing engines and other farm equipment.

Steel dealers on the local market are quite satisfied with the volume of business passing through their hands. It is better than they expected and although competition is keen, they find the total amount closed to be worth while.

A ten per cent. drop in high speed drills is announced. Small tools and general supplies are moving at a fair rate of speed, and continued improvement in this line is looked for.

Machine tools are still quiet, and the scrap market is also rather sluggish.

LOCAL MARKET SHOWS IMPROVED TONE

TORONTO, January 25th.—Steel men in the local market are quite satisfied with conditions. They frankly admit that business is better than they expected it would be, so therefore they are happy. Keen competition exists, and it is the man who gets out in the field that lands the business. Usually the order is not very large, making the situation all the more difficult. To bring up the total of business, it means that salesmen must land just that greater number of orders. Price cutting is still pretty prevalent on this market, but these tactics are confined to a few who did not liquidate soon enough, and now must get rid of their materia.. Some of the figures quoted by these men are so low that they cannot last long. They are altogether too close to the actual mill price to allow deals to make any profit, so that this drag on the market is soon expected to disappear.

One steel dealer speaking on the present situation, referred to a speech of Judge Gary's, made some time ago, when he said that we had just passed through a period of Extravagance and Extortion. "The truth of this remark has made itself felt during the past year, when we have all been getting back to a decent level," remarked this dealer, "but now we are in a much healthier condition," he concluded.

The month of January, taken as a whole, will be a fairly good one for steel men, and they have no reason to complain. The demand is general, no one line being in demand and this again is taken as a healthy sign. Pig iron has dropped in price as will be noted from the quotation pages.

The metal market merely moves along. Non-ferrous red scrap is fairly steady but buyers are not eager to pay the top figure with the result that not many orders are being taken. Copper wire is being offered at 11½ cents, but finds few buyers at this figure. Red brass is selling at 9½ cents and No. 1 red turnings can be purchased in fairly large quantities at from 6¾ to 7 cents. Ordinary yellow casting brass remains a dead issue although the better grades of yellow brass are in somewhat better demand. Even this is not sufficient to take up the surplus being offered. White metal alloys are also very quiet.

Scrap cast iron is merely holding its own, but other grades of scrap iron show signs of weakness. Frieght rates and cost of labor are yet too high to allow any further reduction in scrap prices.

Machine Tools

If enquiries meant orders the machine tool market would be in good shape. Unfortunately however, many of these enquiries die a sudden death, and in fact some having been traced, have been found to emanate from purchasing agents who are anxious to strike the level of current values. Others again write in for a price on a tool, merely to get a figure for inventory purposes, so that when we speak of the number of enquiries, it is no sign of an up-grade market.

So long as factories remain quiet, we cannot expect much improvement in this line. One dealer, who is a firm believer of keeping his men constantly on the road, says "that the only way to get business these days is to go out and dig for it, digging good and hard at that." In these few words he pictures the real situation. Orders are small, therefore to bring up the total, dealers have to work all the harder.

Small Tools

Another good week is reported in the small tool market. Business has picked up quite a bit during the past two weeks, and dealers confidently expect the improvement to continue. High speed drilled, dropped 10 per cent., and it is expected that this decline will stimulate business in this particular line. Farmers are coming into the supply market in good shape, purchasing gasoline engines, and other farm equipment. Generally speaking the market is considerably improved.

STEEL BUSINESS IS STAGNANT; ACTIVE BUILDING SEASON LOOKED FOR

MONTREAL, Jan. 25.—The jobbing houses dealing in merchant bars, plates and structural shapes claim the volume of business at the present time is very disappointing. All through the closing months of 1921 conditions were bad enough, and when this small volume began to disappear entirely in December, there was a tendency to believe it was the Christmas season that was the cause of the depression. However, Christmas has come and gone, yet the condition of practical stagnation still exists. Dealers in this part of the province can advance no reason, and are now inclined to look forward to the seasonal stimulation that is always evident in practically every line of business in the spring.

It has been stated that it is not likely that production of iron and steel will drop to the level of 1921. The out-put of pig iron for the whole world in 1921 was 35,810,000 tons, and the production of steel ingots was 40,731,000 tons. In 1920 the output of pig iron was 60,635,400 tons and of steel ingots 63,321,000 tons. These figures show a big decrease in production. It is interesting to note that in 1913 the pig iron produced in the world was 76,594,000 tons, while in the same year, 74,629,000 tons, of steel ingots were purchased. This comparison shows that we have a long way to go before we equal the production and consumption figures of the pre-war year, 1913.

Conditions Have Changed

Of course it must be borne in mind that conditions have undergone a great change in the last eight or nine years. If our present demands for pig iron and ingots should increase overnight to a figure that was representative of 1913 conditions it is doubtful if such a demand could be supplied. Owing to the destruction of plants, and the dispersal of organizations in central and eastern Europe, the total capacity of the world has been greatly reduced. In fact the world's production figures mentioned above were made up in no small way by the production of Lorraine, of the Far East, and the Antipodes.

It is estimated that the world's capacity to-day is 70 million tons of pig iron, and about 80 million tons of steel ingots. Only 51 per cent. of the blast furnaces were in operation last year, and about the same ratio of steel making units. The production in America has not been quite up to this percentage figure showing that production has been curtailed here to a greater extent than it has been elsewhere.

The prices of steel products have not undergone any changes during the last few weeks, although the present quotations are considered weak. The prospects are good for a very active building season in the province. There are a number of big jobs that have been carried on all winter such as the Mount Royal Hotel, The Canada Cement Building, and the New Low Level Pumping Station.

Pig Iron has dropped two dollars a ton. Unsettled conditions in the States have caused the prices to break, although they were already down to production costs. The Canadian prices were reduced in order that outside iron would not be dumped here. There is no money in it for the producers at this price. Even the reduction has not increased the amount of business being done, although it is hardly time yet to place much weight on this fact. No actual orders have been received but it is a fact that these figures are being used by foundries on all estimates and quotations, so the results of the present reduction may not be felt for some time yet.

Not Much Activity

The machine tool business has not shown any more activity. Dealers do not look for any more than nominal improvement for some time to come. One dealer has recently put out a very elaborate catalogue, and the results from this medium have been very satisfactory so far as the small tool and supply end of this business is concerned. No particular lines seem to be moving, but rather a fair movement of all lines.

Another large supply house reports that business has improved with them a great deal during the last two weeks. Small shop tools and machine shop supplies are in much better demand than they have been for the past month. Throughout the city the report is that the rural people have been buying more or less mechanical equipment. Gas engines have been moving rapidly in the last two weeks. In the maritime provinces the fishing fleets are being fitted out, and activity in marine supplies is rather evident. Every year a large number of marine engines are sold, and an even larger number overhauled.

The non-ferrous metals have not been active the past week, but prices have been very weak and several reductions in quotations have been received, as will be noted on the quotation page. The scrap metal market is still very quiet.

Interesting Books:

"Industrial Mathematics Practically Applied," is the title of a book by Paul V. Farnsworth, published by the D. Van Nostrand Co., 8 Warren St., New York. It contains over 1,000 problems and answers, and has 250 illustrations which are very well arranged. This work is claimed to be the result of 12 years' experience by the author as supervisor of apprentices, designing, shop foreman, and instructor in evening classes in technical schools. Every attempt has been made to simplify and analyze, step by step, the various problems, and the author has succeeded in making the examples both practical and instructive.

He starts with signs, symbols, etc., goes through addition, substraction, division, cancellation, and so on, working up gradually into ratio and proportion, going from here into square root, mensuration, geometry, cost calculations, gearing definitions, lathe change gears, rope drives, shaft design, strength of materials, and many other subjects of interest to the student, and ambitious mechanic.

To go into all the subjects discussed in the 274 pages is impossible in this space but any reader desirous of brushing up or learning afresh, the many subjects covered, will find this book interesting and thorough. The publishers price is $2.50.

Another interesting book, published by the same company is titled "Centrifugal Pumps," and sells for $3.75. The author J. W. Cameron, A. M. I. Mech. E., starts off by describing the action and advantages of Centrifugal or Turbine pumps. The chapters following the introductory one touch upon the following subjects:—The theory of the centrifugal pump, hydraulic losses during the passage of fluid, manometric head, change of pressure, and hydraulic efficiency.

Then comes disc friction bearings, effect of angle at discharge on the efficiency of pump, details of construction, axial thrust and its balancing, calculaton and design of a single stage pump, then the same on the multi-stage type. Chapter eleven discusses various types of pumps, this being followed by methods of testing.

This book is chiefly arranged for engineers, draftsmen, and designers, and the author has been very careful in his descriptions. The subject is one on which little is known by the average draftsmen, so that the book will no doubt be welcomed by those in the profession.

NEW TYPE LOCOMOTIVE TO BE GIVEN TRIAL

E. R. Webb, of the St. Thomas division of the Michigan Central Railway states that a new passenger locomotive is to be given a 90-day trial on this line.

It is considered one of the fastest of its kind on the North American continent, and will be used for hauling the Wolverine and the Detroiter. Among railroaders the engine is known as the K-3 model. The other day another fast run was made over the division. Train No. 15 travelling from Windsor to St. Thomas, a distance of 112 miles, in 91 minutes.

W. A. Grayson, manager of the Washington, D. C., plant of William Jessops & Sons, Sheffield, England, is going to England on a business trip shortly. He sails on February 15th.

News From the Industrial Field

INDUSTRIAL NEWS

Leslie and Hardy, Georgetown, Ont., are in the market for machinery for making skates.

The Board of Waterworks, Essex, Ont., is in the market for oil engines to operate their waterworks pumps.

The city engineer of New Westminster, B. C., is preparing plans for reconstruction of water works plant and system to cost $250,000.

The Carter White Lead Co., of Canada, Delorimer Avenue, Montreal, Que., has awarded a contract for plant revision to cost $13,000.

The Standard Steel Construction Co., 29 Cross St., Welland, Ont., has the steel contract for a factory for the Universal Cement Casket Co., London, Ont.

The Harper-Fresnail Cigar Co., Hamilton, Ont., will resume operations to the full capacity of its plant the first of next week. This will give employment to 150 men.

The Hiram Walker Metal Products Co., Walkerville, Ont., is overhauling its foundry and installing the latest equipment for handling grey iron castings on a productive basis. Included in the equipment is a Whitney self-feeding cupola. A separate building is being fitted out for the production of Chromel wire.

The manufacture of Vacuum Cleaners on a large scale is intended by The Mis-Can-Ada Mfg., Co., 12 Chamberlain Ave., Ottawa, Ont., recently incorporated at $65,000. The company does not intend to build a plant, as a lease has been obtained for suitable quarters, but do expect to be in the market from time to time for machinery and supplies.

Quite a cheery view of the business situation is taken by Mr. H. B. Christie of the Sawyer-Massey Company, Hamilton, Ont. He says that although the present is by no means the busy season of the year for his company, they have taken on since the first of the year, over one hundred additional men and that more were being taken on daily.

Captain S. J. Gregg, of the Toronto Carpet Co., says his firm is operating overtime, running the plant 55 hours a week. Moreover, he says the outlook for the next six months in the carpet industry is a very satisfactory one. Production at the present time is solely for the Canadian market. A number of United States orders were filled last summer and autumn, owing to strikes at the American mills, but the last of these were completed about a month ago and the goods being turned out at present are for the domestic trade.

The city council of Blenheim, Ont., is planning an electric light and power distribution system to cost about $40,000.

The Utilities Board of Simcoe, Ont., plan to install additional equipment in electric light plant to increase its capacity.

The factory owned by the McCarter Shingle Co., Rock Avenue, Victoria, B. C., was damaged by fire with a loss to building and machinery of $60,000.

Contracts for structural steel and steel stairways required for Ottawa schools, costing $700,000 have been awarded to the Dominion Bridge Co., Montreal.

The Goderich Elevator Co., London, Ont., are in the market for grain handling and unloading machinery, also two steel unloading towers for grain elevators at Goderich.

The Verity Plow Co., Brantford, Ont., have announced that within the next few days from fifty to one hundred additional men will be placed on the payrolls.

The Sarnia Paper Box Co., Sarnia, Ont., whose capital is being increased to $300,000, and who are going to move to London, Ont., is in the market for machinery and equipment for the manufacture of fibre and corrugated shipping containers.

After being closed for about three weeks, The Rail Mills, Blooming and Open Hearth Furnaces of the Dominion steel plant will resume work within the next few days on a 10,000 tons rail order for the Grand Trunk. This work will take over a month and will give employment to five or six hundred additional men.

An industrial survey for the province of Alberta is being made through its trade commisioner. The purpose is to inquire thoroughly into the industrial situation, taking into consideration the number and kinds of industries, whether or not they are working on full time, and if not, why not. This will be with a view to giving assistance later in the widening of existing markets for Alberta products.

Work on the International bridge between Sandwich and Detroit will start within 30 days according to a report from Windsor. The Sandwich Town Council has given permission to the bridge company to drill at certain locations and to ascertain the nature of the strata, depth and strength of foundation rock. The exact location of the Canadian end of the bridge has not yet been determined, but the action of the engineers in seeking permission to drill at Sandwich would seem to indicate that this location is favored.

Over 500 engineers from all sections of Canada will assemble in Montreal from Jan. 24-25 at the annual general meeting of the Engineering Institute of Canada.

The Sarnia Collegiate Institute and Technical School is nearing completion and is now ready to purchase machinery and equipment for the several departments.

The Sarnia Collegiate Institute and Technical School is nearing completion, and they are about ready to purchase necessary equipment for this building, according to the secretary of the Sarnia Board of Trade.

Conditions are very satisfactory at the plant of the English Electric Co. of Canada, St. Catharines, Ont. Inquires for new equipment are numerous, and orders on hand are sufficient to keep the factory busy for some time.

The Clyde Shipbuilders anticipate, with confidence, much busier times shortly. Work has been resumed on a number of vessels, principally of the passenger type. Returns for the Clyde Area for 1922 show 249 vessels of 511,000 tons completed, against 330 vessels of 672,000 tons in 1920.

London, Ont., has suffered from a $350,000 fire. The three firms affected are: The David Cowan hardware store, loss $100,000, The Morrison Shoe Co., loss $50,000, and the Stafford Furniture Co., whose stock was absolutely wiped out. It is contemplated that these business buildings will be re-erected in the very near future.

Quebec will spend $1,000,000 for new roads, and a similar amount for maintenance, also a further million for education according to a statement made by Premier Taschereau a few days ago.

The Canadian Natural Clay Products Association will hold their convention in Toronto on Feb. 7th, 8th, and 9th. Various papers will be presented.

The attendance of buyers at the annual Furniture Exhibit at Kitchener, Ont., for the past ten days has exceeded all previous records. Buyers have come from all parts of the Dominion. Most of the manufacturers in that vicinity who have exhibits report splendid orders which will keep factories busy for months to come.

Industrial conditions show signs of improvement over the past week end. The W. E. Sanford Mfg. Co. announce that it has increased its staff to 75%, the number of regular employees hired during favorable conditions. The clothing industry was hit hard after the war, but an official of the Sanford Co. says there are now indications of better times.

The National Fibre Co., of Canada, a new concern have located in Toronto. Sales office will be at 220 King St., West.

A by-law has been passed by ratepayers in Niagara Falls, authorizing the expenditure of $40,000 for construction of an asphalt plant.

The Drake Engine Company, of Grand Haven, Mich., have opened a Canadian Sales office at 45 Adelaide Street, Toronto. Capt. Stitt is in charge.

A bridge is to be constructed across the Gatineau river at Gracefield according to a report from Ottawa. Construction will start early in the summer and will take about two months to complete.

Plans have been prepared at Truro, N. S. for a hospital to cost between $75,000 to $80,000. Two sites are being considered and the Council have been asked for a further grant to help along this work.

The ratepayers of Port Arthur, Ont. have passed a by-law authorizing fixed assessment and other concessions to the Provincial Paper Mills, Ottawa, Ont., in connection with the erection of a mill which will cost $1,500,000.

The month of December closes a successful building year at Niagara Falls, Ont., there being a total of 263 permits issued, valued at, $1,145,589. These figures show a large increase over the previous year, when only 133 permits, valued at $473,065 were issued.

Mr. A. Milton, 67 Frederick St., Toronto has been appointed the Ontario representative for George Ellison, & Co., of Birmingham, England who manufactures electrical control equipment of all kinds. This concern are going to carry a considerable stock in Toronto, and Mr. Milton is looking for good business in this line during the year.

A new six-story hotel may be built in Sault Ste. Marie. The site proposed is that of the present Windsor House and a plan whereby the city will be called upon to guarantee bonds to the amount of $250,000 is being drafted. The total cost of the new hotel is placed at $600,000 and the board of trade will conduct a campaign to have a by-law, which is to be submitted to the ratepayers, carried.

The Victoria Machinery Depot, Victoria, B. C., has been awarded the contract for repair work to the Canadian Pacific car ferry No. 8, driven ashore last month at Porlier Pass and later salvaged by the Canadian Salvage Company. The figure is understood to be in the neighborhood of $50,000. The same firm also has the contract for the overhauling of the C. G. S. Newington, the lighthouse tender operated by the Prince Rupert Agency of Marine. A new tail shaft will also be fitted to the steamer. The Newington is now southbound and expected in a few days at the Upper Harbor yard.

The Ford Motor Car Co., of Canada, have acquired the plant of the Bain Wagon Works, Woodstock. This plant will be used exclusively for the manufacture of Ford trucks.

The Wayne Forge & Machine Co. report business as very encouraging. They recently sold a heat treating furnace to a Toronto can factory, to be used for the tempering of dies, etc.

Building figures for Windsor, Ont., for 1921 show an increase in permits to the value of $123,270. In 1920 1,109 permits were applied for, the value of which were estimated at $4,850,010.

Construction of the Lloyd George Hotel, London, Ont., will be started within a month. Anglin-Norcross Co. of Montreal, will handle the construction work and the approximate cost will be $1,500,000.

Hugh Stewart, formerly with the H. W. Petrie Co., Toronto, has joined the staff of the Albert Herbert Ltd., 1-3 Jarvis St., Toronto. He will act as salesman on all lines handled by the latter mentioned firm.

The Vulcan Co., 84 Fulton St., London, Ont., manufacturers of iron castings and equipment are in the market for metal working machinery, lathes, planers, shapers, welding equipment, riveters and beltings.

The Rose Co., dealers in industrial diamonds have discontinued their Toronto office. All Canadian business in the future will be handled from the New York office. E. Weimer their Canadian sales representative has gone back to the New York office.

The Canadian Fairbanks-Morse Co., Montreal, state that the business closed in their small tool and machine shop supply departments has increased to a very marked extent during the past two weeks. During the last two weeks in December, and the first week in the New Year, very little business was offering but the volume closed in the last week has been quite up to that of last autumn when conditions were very satisfactory in this department. The rural population have been purchasing very freely of late this firm states. Gas engines, pumps, and many specialties for farm use are moving quite nicely.

The production of pig iron in November for the Dominion was fairly well maintained. The total of basic iron amounted to 41,232 long tons as compared with 42,356 tons in the preceding months. The production of ingots and castings in November showed a decided improvement, the output rising from a high record of 72,204 long tons in the month just closed. Of the November output 73,806 tons were made by the producers for their own use mostly in the manufacture of steel rails. A small amount was produced for direct sale, the total under this item being 1,233 long tons practically all of which was in the form of steel castings.

Fire damaged the foundry plant of McLean, Holt Co., St. John, N. B. to the extent of $20,000.

The Columbia Macaroni Co., Lethbridge, Alta. contemplate building a $50,000 plant, which was recently destroyed by fire.

Fire losses in Canada during the week ending December 28th were estimated by the "Monetary Times" at $716,000, compared with $798,600 the previous week.

The erection of a bank building to cost $400,000 is proposed by the Bank of Montreal at Victoria, B. C. Erection of an Agricultural Building at the cost of $25,000 is contemplated by the Provincial Government to be erected at Ste. Joseph, Quebec.

The Canadian Manufacturers' Association is sending out a circular among its members with a view to ascertain how many will partake of a tour of the British West Indies under the auspices of the association. The itinerary, after leaving Halifax on February 17, includes the most important points in the islands and is expected to last 60 days. The object of the visit is to investigate the possibilities of trade between Canada and the West Indies.

Construction contracts awarded in the Dominion of Canada for the month of December, 1921, totalled more than $19,000,000. The construction work which was contemplated for December, 1921, amounted to $14,000,000. The total contracts awarded for 1921 in the Dominion had a total of $240,133,300. Industrial buildings erected in 1921, for the Dominion totalled approximately $13,000,000. This item of course does not include business buildings such as offices, etc.

Mitchell, Ont.—The Wettlaufer Co. manufacturers of concrete machinery, is making preparations for the erection of a one-story building, 75 feet wide by 80 feet long, of concrete and steel. The new addition, which will be in the rear of the main factory, will be used as an erecting shop, and will have a traveling This firm which ships its cement mixers crane running through the centre of it and other machinery to all parts of the wordl, even as far as China, intend to employ a larger number of men during the coming spring and summer months.

It will be noted from the following figures that there were 200 branches of Canadian Banks opened during 1921 as compared with 135 branches closed, which makes a net gain of 65 new branches. The period responsible for this increase was February, March and April 1921. In February, 15 branches were opened and only four were closed, in March 10 were opened and seven closed. In April 24 branches were opened and seven closed. There was only one month in the year when the total of branches closed exceeded that opened. This was in December when eight branches were opened and 25 closed.

BRITISH TENDENCY TOWARD LARGE CAPITAL ORGANIZATION

A STRONG tendency toward large capital organization is evident in the industrial and financial life of Great Britain, according to the National Bank of Commerce in New York. Wartime expansion of post-war foreign competition, it declares, have led to consolidation and larger resources at the expense of the smaller individual enterprises.

"The impulse toward consolidation of interests and resources which produced in America the United States Steel Corporation, the Standard Oil Company and the Ford organization has in recent years been felt with particular force in British industry," the bank says in the December issue of its magazine, Commerce Monthly. "The desire for expansion of enterprise during and after the war and the need for liquid capital to maintain expanded enterprise in the face of tightening conditions were alike conducive to enlarging the capital of commercial and industrial companies. Fear of foreign competition emphasized the desirability of eliminating by amalgamation or agreement major competition at home and of securing the resulting economies in production. Either course tended to produce large organizations with extensive capital resources at the expense of the smaller individual enterprises which have played so large a part in the industrial life of Great Britain.

"Besides new organizations which sought capital during 1919 and 1920, numerous long established companies increased their capital either for the purpose of expanding business, extending plant or purchasing allied concerns. New issues of capital for commercial and industrial purposes in Great Britain in 1920, exclusive of conversion loans, bonus shares, and shares issued to vendors, amounted to about three times prewar amount in 1919. In the first nine months of 1921, however, the general business depression was clearly reflected in a marked decrease of new capital issues. The largest relative expansion occurred in the iron, steel, coal and related industries, miscellaneous commercial and industrial enterprises, banks, motor traction, and breweries.

"A second characteristic of the period is the number of amalgamations which took place. This was in many instances but the continuation of a movement which had been going on even prior to the war, notably in the iron, steel and coal, and the textile industries.

"In contrast with the elaborate anti-trust laws of the United States, the common law is practically the only check upon combinations in Great Britain. It holds null and void agreements in restraint of trade, but is has been broadly construed and considerable weight is given to freedom of contract, so that combination is not prohibited. Existing combinations range all the way from associations somewhat resembling the German cartel, in which each firm retains its identity and its independence in all save certain specific matters controlled by the association, to complete amalgamation.

"Recent tendencies appear, however, under the pressure of external competition, to be definitely away from this type of more or less temporary co-operative organization and in the direction of permanent control through amalgamation or through share ownership in subsidiary companies. Many of the largest capital issues in 1920 were for this purpose. Corporations or holding companies of this kind do not require for their success the inclusion of practically an entire industry and they make possible economies of production as well as regulation of output and selling price. Their effect upon price has a very definite relationship to the extent of their dominance in the field of industry concerned, but through the advantages of a large scale organization technical knowledge, makes possible they can exist on a competitive basis while a monopolistic position is being attained.

"The tendency toward large scale organization of industry and capital is a natural step in the progress of industrial evolution, continues this report, as it provides greater resources, encourages the development and inter-change of economies of production, and lessens the variety, if not always the severity, of competition. There are, however, offsetting influences to this development. The size of plant and organization which can be handled economically under single control has definite limits. Moreover, the effect of large scale organizations upon the whole economic and social structure cannot be overlooked. The far-reaching results of the failure or disintegration of a large concern might tend to prolong its existence beyond economic usefulness. The influence upon workmen, likewise, of a scale of production which destroys the sense of craftmanship is already being felt throughout the industrial world in unrest and loss of efficiency.

"Great Britain appears still to be under the influence of centripetal forces. In some of the most important industries, which had long since sought the international market for their products, the tendency toward consolidation appeared before the war, and recent developments represent merely a continuation and to some extent an acceleration of the movement. Other industries seem definitely to have arrived at this stage of progress since the war. In general, the movement appears not to have advanced so far in Great Britain as in the United States. In the face of keen international competition, both prospective and actual, however, British industry appears to be approaching rapidly to the stage of large corporate organization."

NEW IDEA IN STEEL— IDENTIFICATION AND STORAG

IT often happens that, due to an absence of standard equipment on th market, or lack of a standard way o doing things, manufactuers are force to create new methods or devise ne equipment that will exactly fit int their particular system of operatior With the result that the new idea evolv ed and executed is generally an im provement over everything of a simila nature that has preceded it.

Such a condition caused the firm o Gould & Eberhardt to devise the fol lowing method of marking their stee bars for identification and also de signing and constructing suitable stee storage racks to conform with the high ly developed manufacturing system em ployed in their new plant at Newark New Jersey. Several new ideas in stee marking, together with a novel desig in storage racks is the result of thei efforts to solve their own factory prob lems.

In the manufacture of shapers an automatic gear cutting machinery, the use many different kinds and sizes o steel bars—round, square, hexagon, an rectangular in shape, so that the nev system of storing and marking the var ious grades and sizes entirely elimin ates the possibility of an error in find ing the required piece.

Colors Play Important Part

Plain colors and combinations of col ors play an important part in the scheme of marking the steel, each color hav ing a direct significance with regar to the metallurgical contents or the particular make of steel. The identifi cation colors are painted on the ends of the bars as they are received in the shipping department.

To assist the raw material clerk in selecting the proper steel, a very noticeable identification board is hung above each rack. On this rack are listed all the different kinds of steels the company uses, with a two inch diameter disk, painted in the corresponding color, opposite each name. The board has a white background which shows the various colors to great advantage.

The various steels with their corresponding colors as listed on the board are:

30-45 Machine	Red
Hy. Speed Tool	Blue
Crescent	Yellow
10-15 Machine	Green
Cold Rolled	White
O. C. N. S.	Halves of Green and Red
Simplex	Green with White Stripe
Tap	Halves of Green and White

Each rack is built up of five duplicate sections, spaced four feet apart and properly braced to form a very rigid rack sixteen feet long. The entire rack being bolted together with one-half inch bolts.

The individual section has a base consisting of a heavy eight inch I beam eight feet long, with six heavy 2 x 2

No Matter What it is that You May Need—

If It's Machinery

We Can Supply You

JUST tell us what you need—we can supply you. We carry the largest stock in Canada of iron and woodworking machinery, foundry equipment, boilers, motors, fittings and precision tools of all descriptions.

The "Williams" organization has been built up on service. If we don't happen to have just what you want, we can get it—and get it quickly.

Tell us what you need and a prompt reply with a "right price" quotation will be sent by return mail.

Write us to put your name on the mailing list for our regular monthly Machinery List.

Montreal TORONTO Winnipeg

inch angles, seven feet high, equally spaced and forming uprights to divide the section into five tiers. These tiers are in turn subdivided by one-half inch rods which extend from top to bottom thereby making ten tiers available in each rack.

Cross pieces or shelves on which the steel bars lay are heavy 2 x 2 inch angles, spaced about twenty inches above each other at bottom and diminishing in this distance until at the top, where the very small rods are stored, the distance between is about six inches. The top piece of each section is composed of a heavy 2 x 3 inch angle, making a very rigid top brace to complete the frame of the section, and also permiting the storage of extra large diameter short bars on top of the rack.

The five cross sections are spaced and held together to form the completed frame work of the rack by 2 x 2 inch heavy angle stringers extending the full length of the rack at the top and bottom of each side. Extra longitudinal bracing is provided by ¼ x 2½ flat bars crossed between and bolted to the top and bottom of the sections.

An extra angle on each side at the top and extending the length of the rack prevents pieces from rolling off, while further precaution is taken by having timbers with half round notches cut in them extending along the front on top of the rack, permitting short round pieces to be layed in place.

Naturally, the most convenient way to place the steel in the rack would be to have all the steel of the same kind in one tier with the largest and heaviest pieces on the bottom shelf and the varying sizes in regular order, according to their dimension, with the smallest at the top. This order has been reversed wherever possible, in some cases the square, hexagon, or rectangular shaped bars, which are generally smaller in size, being placed on the bottom shelves and the very heavy bars on the very top so that they may be easily handled with the travelling crane which travels above these racks.

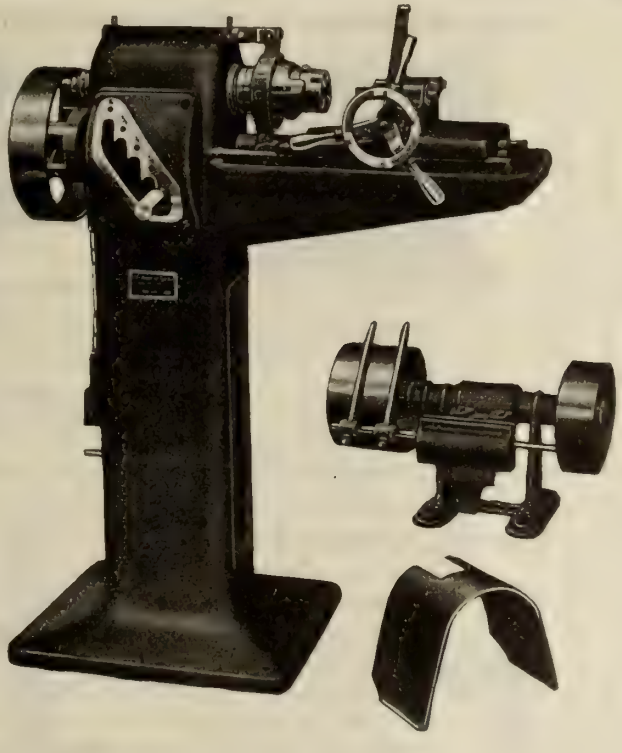
You Received Full Value

It is easy to judge the size and quality of a visible commodity. There are certain recognized standards that have been universally accepted to which purchased articles may be compared.



With invisible commodities, such as a publication's circulation, the matter is not so simple. It was only recently that a definite measurement has been obtained.

The A. B. C. now furnishes a recognized standard by which circulation may be measured. A publication's distribution can now be as accurately gauged as any other purchased commodity.

The Canadian Machinery circulation is measured by the A.B.C. In buying advertising space in its columns you receive dollar-for-dollar value.

4,000 Threads in One Day

With a Geometric Threading Machine a thread .891″ Diam., 32 pitch, V, 7-16″ long, is cut on 4,000 Graphophone Brass Mouth Pieces in one day. Before the work was put on a Geometric Threading Machine, a solid die was used, and, with the necessary backing off, only 800 pieces could be threaded in one day.

Geometric Threading Machines give production increases that mean much. Send for the booklets. There are the Single Spindle, Double Spindle and Bench Threading Machines.

Canadian Machinery BUYERS DIRECTORY

If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index—last page of book, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

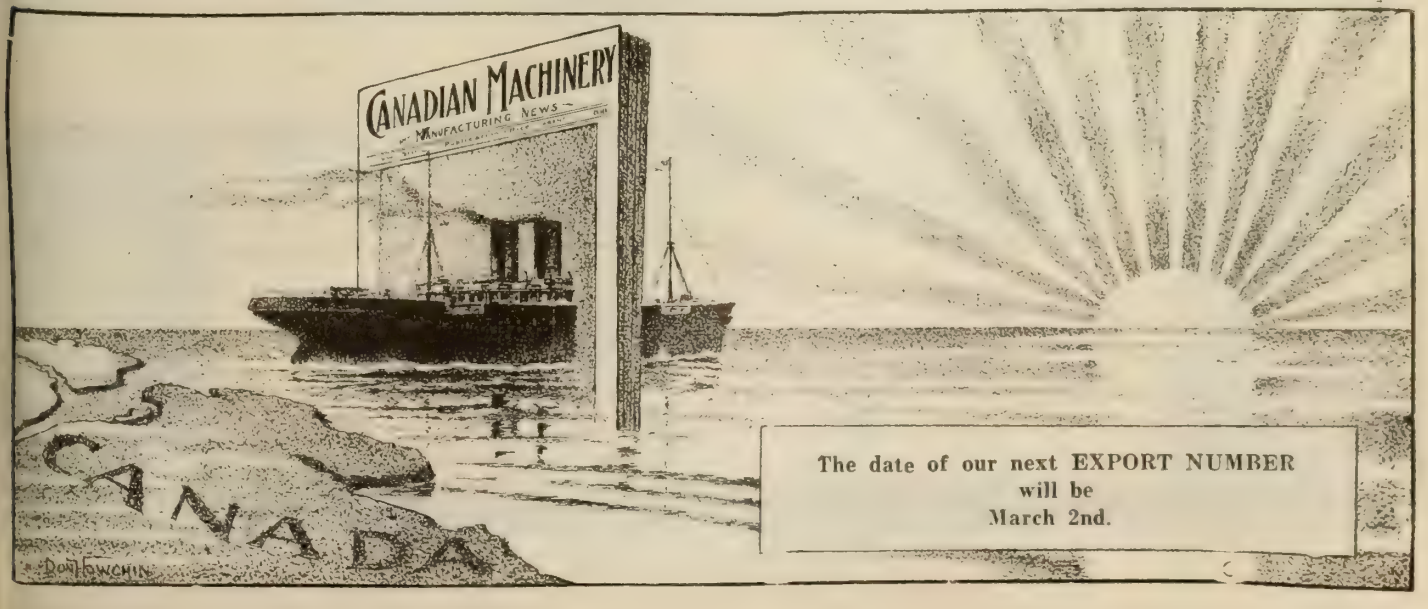
WANTED — A LATHE AND GEAR CUTTER. Must be in good condition. Advertiser desires to get in touch quickly with any person who is able to offer same. Apply Beaver Machine Shop, 1110 Center St., Calgary, Alberta. (c5mlg)

MACHINE WORK WANTED



MACHINE WORK WANTED FOR LATHES, shapers, milling machine and planer, etc. Hourly or contract basis. Prompt delivery. W.H. Sumbling Machinery Co., Toronto. (etfm)

EQUIPMENT WANTED

CAFETERIA EQUIPMENT — RANGE, STEAM table, glass shelving, urns, Cash register, etc. Must be in first class condition. Give description and prices. State where may be inspected. Box No. 801L, Canadian Machinery.

RATE FOR CLASSIFIED ADVERTISING

Rates (payable in advance.): Two cents per word. Count five words when box number is required. Each figure counts as one word. Minimum order $1.00. Display rates on application.

The date of our next EXPORT NUMBER will be March 2nd.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

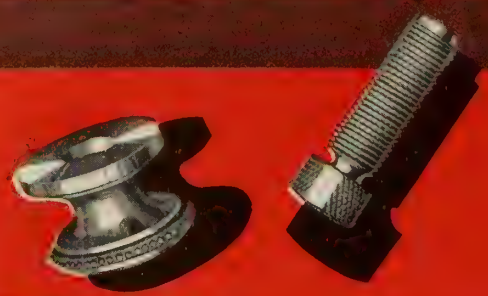
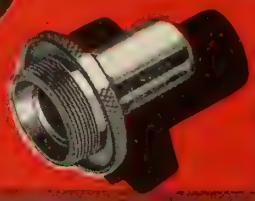
OPERATED IN CONJUNCTION WITH A CONTINENT WIDE NET-WORK OF DISTRIBUTION STATIONS

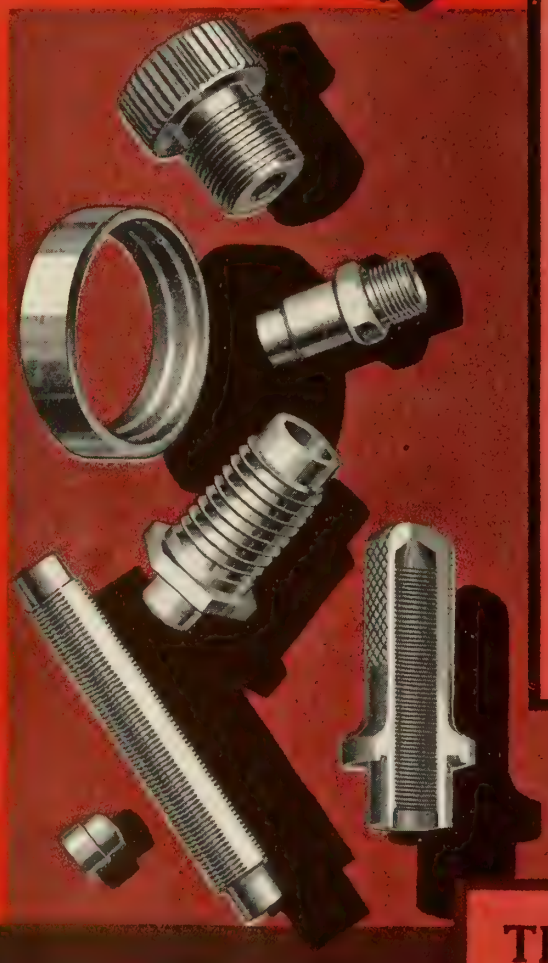
"Liquid Air" Oxygen Means a Saving in Transportation



With a network of Factories not only planned, but in actual operation, and a number of Distribution Stations situated at all large centres all over Canada, Purchasers of Oxygen can obtain their supplies at a point very near to the point of consumption. This completely obviates heavy freight charges on cylinders and assures an immediate supply at any time within a few hours and even minutes after the orders are placed.



All cylinders conform to the specifications of the Canadian Railroad Board and are made to ensure safety without unnecessary weight. When purchasing "Liquid Air" Oxygen you not only save on freight, but in very many cases this expense is almost eliminated.



Namco Parts
For Auto Accessories

It makes no difference whether you need—One thousand tiny Adjusting Screws—Ten thousand Hardened and Ground Spring Bolts—or any other kind of milled parts up to 2¼ in. diam. Our well-equipped product plant is at your service.

Extensive knowledge of special operations and a mechanical equipment for practically every variety, enables us to take care of new and highly specialized products without the loss of time caused by slower methods, or the cost of experimenting to find quicker ones.

Standard Cap and Set Screws, also Finished Nuts and Studs from stock.

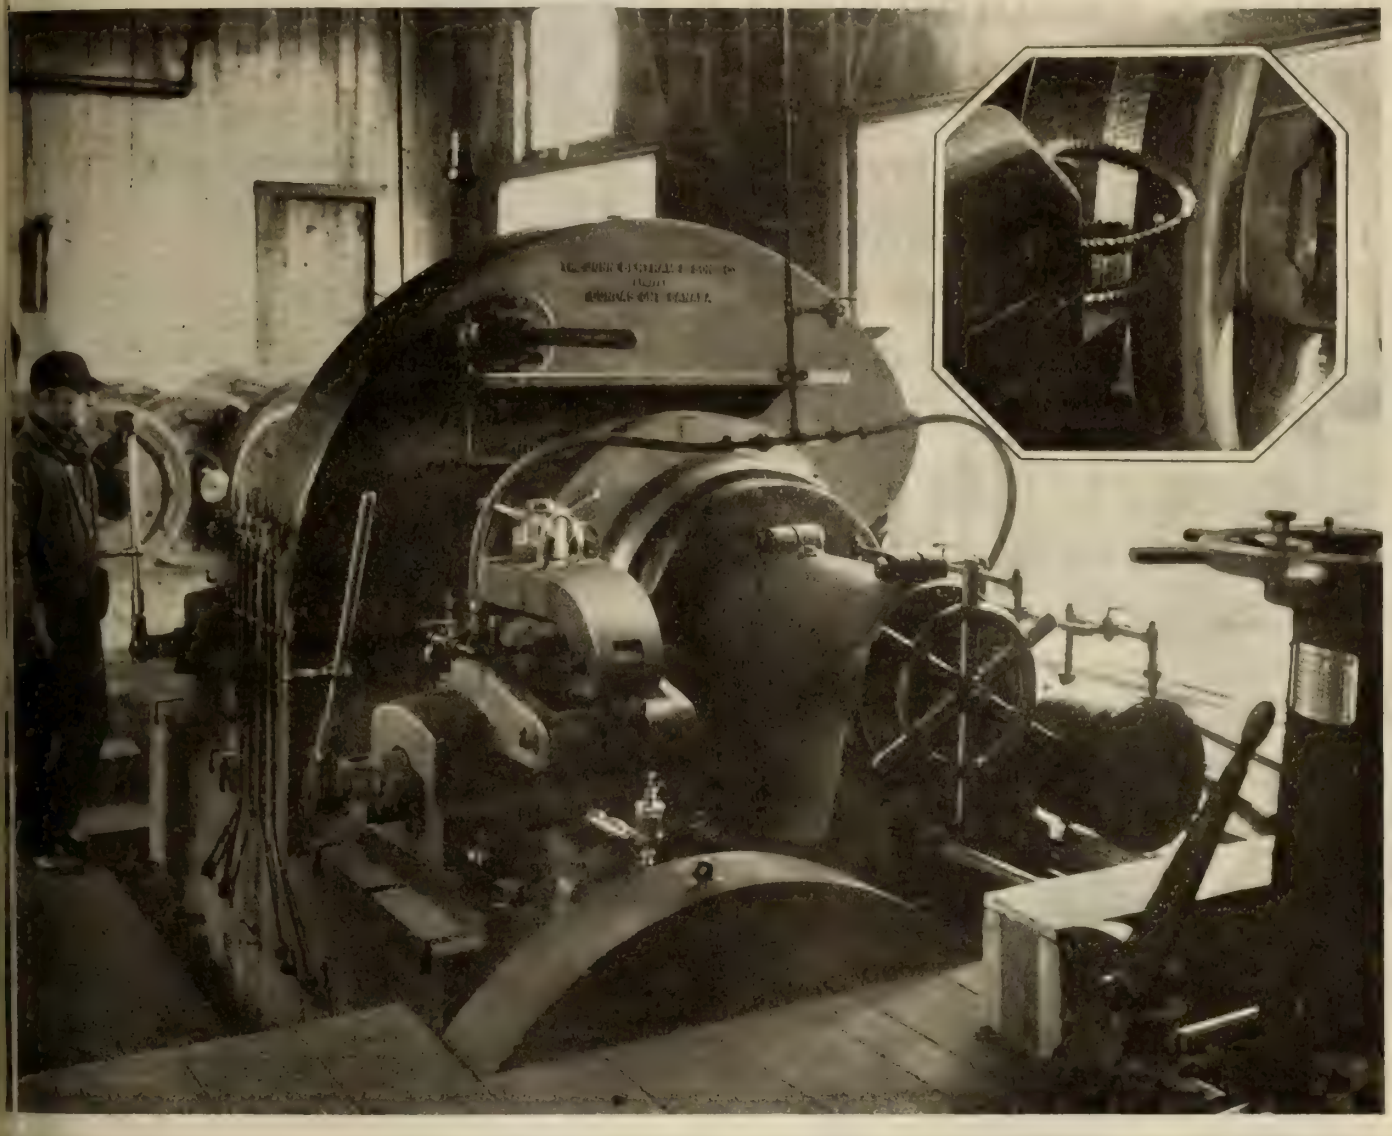
STAYBOLT TAPS

The Better the Man, the More He Appreciates Them—

Not only good when new, but heat treated and seasoned to maintain this goodness. Can be ground on face of cutting edge without affecting their size. That's why you'll find Pratt and Whitney Stay Bolt Taps on the job long after cheaper, "just as good" tools are buried in the scrap pile.

Threads accurately and cleanly cut, with the least expenditure of time and effort, are other reasons why these better Taps are favorites in the shop.



If you've used them before, you know just how good they are. If you haven't, send us your first order—we know you'll be back for more. They're carried in stock in our sales rooms in all large cities.

You pay your workmen well for their time and effort: don't waste this labor-element by keeping dull files in use.

A file ceases to be fully efficient as soon as it has begun to lose its keen-cutting edge. Replacing it costs only a trifle but means much in increased efficiency.

These brands, the standard for over fifty years, do not dull quickly:—

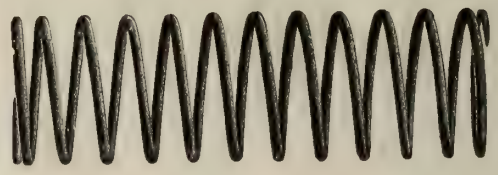
Confidence

Fifteen years and more is not an unusual length of service for Bristol's Recording Instruments. In many industrial plants there may be found recorders which have been in constant use for this length of time. We are proud of these "old recorders"—they stand for just the sincerity and reliability we have endeavored to put into them.

Time and Service Tested

TRADE MARK
BRISTOL'S
REG.U.S.PAT.OFFICE

Recording Instruments



have earned the confidence which could not be gained otherwise. They have proved beyond any doubt that the performance in service is all and more than we claim.
The ever growing demand for recording instruments is shown by the fact that a little over thirty years ago the only recording instrument was a pressure gauge, while now our line includes: Recording Instruments for Pressure, Vacuum, Temperature, Electricity, Time, Motion, Speed, Humidity, etc.

Get copy of information Bulletin 1-303, *telling about this line of Recorders.*

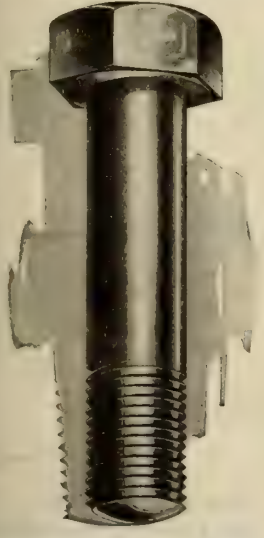
Cut the Cost of Handling Oil

Save time and labor, eliminate oil losses and reduce the fire and explosion hazard in your plant by installing Bowser Piston-Type Measuring Pumps for handling oils.

Bowser Pumps deliver clean oil quickly and conveniently. Bowser all-metal, leak-proof construction eliminates losses by leakage and gumming. Positive mechanical stops assure accurate measurement. Spillage is thus eliminated. Rapid handling in convenient locations saves *time*.

More than a million Bowser Pumps have been installed during the last 35 years. The experience of their users is a safe guide to economy.



No matter what your needs, there is a Bowser to meet them

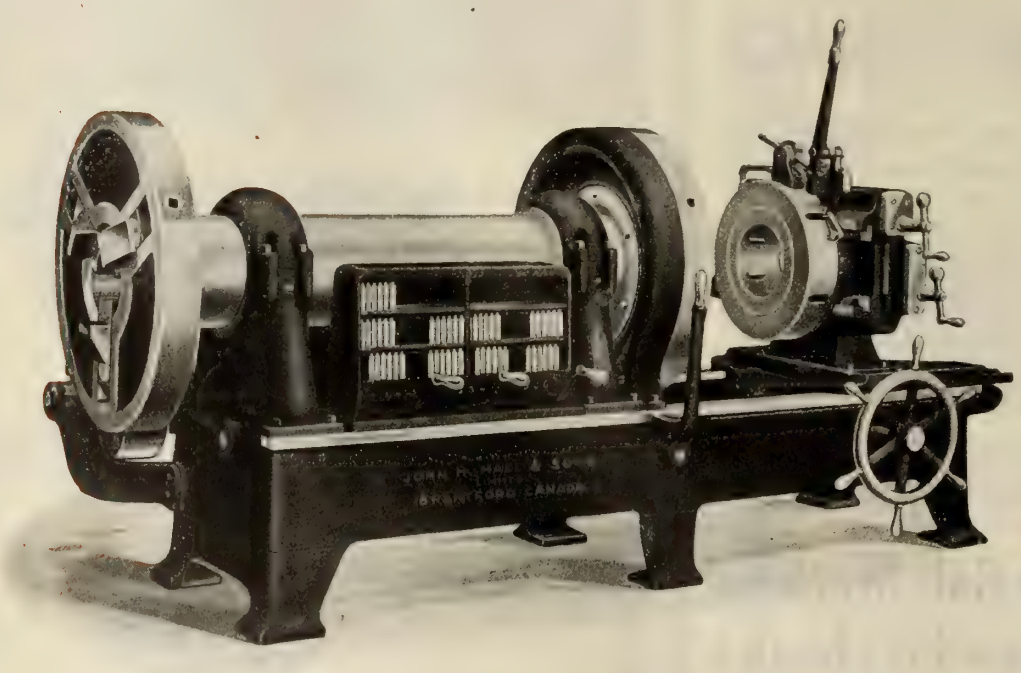
HESPELER, ONTARIO

When Canadian Hall Joined with U.S. Williams

A Great Day for Pipe Machine Users

IN CANADA when you think of pipe machines, the name Hall immediately comes to mind. In the United States it's the Williams machine that has won the reputation to thread pipe better, quicker and at lower cost. Now the advantages of both are combined in each. They have joined forces and the Hall is now the Williams of Canada.



Whether it's 1-8 inch or 16 inch pipe or any of the sizes in between, there's a Williams machine just right for the job. Built in eight sizes and each size especially designed to meet the requirements of the case. And remember, each Williams machine is backed by the combined features, experience and service of Hall of Canada and Williams of the United States, each a firmly established leader in its field.

You who do or should use power pipe machines will do well to write for the details of how and why this merger means greater economy, production and efficiency in pipe threading practice.

Ask for the new Williams' handbook "Don't Let It Happen To You."

Williams Tool Corp. of Canada, Ltd.

U. S. Plant: Erie, Pa.

The illustration is of our No. 8 new improved Duplex Type Standard, capacity 2½" to 8" inclusive.

WILLIAMS PIPE MACHINES

ENGINEERS

Look to Your

BELTING

In quiet periods, put your mills and factories through a scrutinizing search for means of mechanical improvement. Perhaps the first thing you notice will be that the Belts on many machines need replacing or repairing. For the sake of efficiency in lasting qualities and in effective transmission, make your next requisition for belting call for—

"P.M.S" Belts

Maximum Endurance and Efficiency for all Uses.

Branches in all Leading Canadian Cities.

"ULOY" STEELS

With our immense plants we are in position to furnish all commercial analyses in open hearth and electric furnace steels. Rolled into bars, billets and slabs. Annealing, heat treating and cold drawing done according to your specifications.

There is a ULOY steel for each purpose. For automobile, truck and tractor parts; for ball bearings, axes, hatchets, wedges, agricultural implements, lumbermen's tools, track tools, shovels, picks, beater bars, coal crushers, piston rods, locomotive main and side rods, springs, shear knives—A few of these steels are:

Chrome-Vanadium	**Hi-Carbon**	**Chrome-Carbon**
Nickel	**Chrome-Nickel**	**Magnet Steels**
Chrome-Molybdenum	**Silico-Manganese**	**Special Analyses**

What is **your** product? If an alloy steel can be used to advantage in its manufacture our engineers will be glad to assist you in the selection of the proper grade and type. Write, giving full details.

UNITED ALLOY STEEL

Open Hearth and Electric Furnace Alloy Steel for Railroads, Automobiles, Edged Tools and Agricultural Implements.

Toncan Metal for Safety and Long Service

Toncan Metal is anti-corrosive and, therefore, it was used for the roofing and flue work for the famous Chateau Frontenac Hotel, Quebec, because its long life makes it most economical. It has served here since 1915 and is still in excellent condition. Thousands of installations both in Canada and the United States testify to Toncan Metal's lasting qualities. Those made over twelve years ago are still good.

TONCAN METAL

The Iron that Endures and Insures

Where atmospheric conditions are severe specify anti-corrosive Toncan Metal. It endures. Also has superior forming and welding qualities. Write for complete information. A few well-known uses for Toncan are:

Roofing	Cornices	Culverts
Siding	Skylights	Tanks
Eaves Trough	Window Frames	Lath
Conductor Pipe	Smoke Pipes	Refrigerators
Flashing	Water Pans	Washing Machines
Valleys	Ventilators	Enameled Products

CORP'N, CANTON, OHIO, U.S.A.

In Canada: Toncan Metal is Galvanized by Dominion Sheet Metal Corp'n, Ltd., Hamilton, Ont., Fabricated by The Pedlar People, Ltd., Oshawa, Ont.

THERE is as much difference in the various makes of High Speed Steel as there is in men—

The practice and methods of manufacturers differ widely in every mill and anyone who is at all familiar with the manufacture of High Speed Steel thoroughly understands this

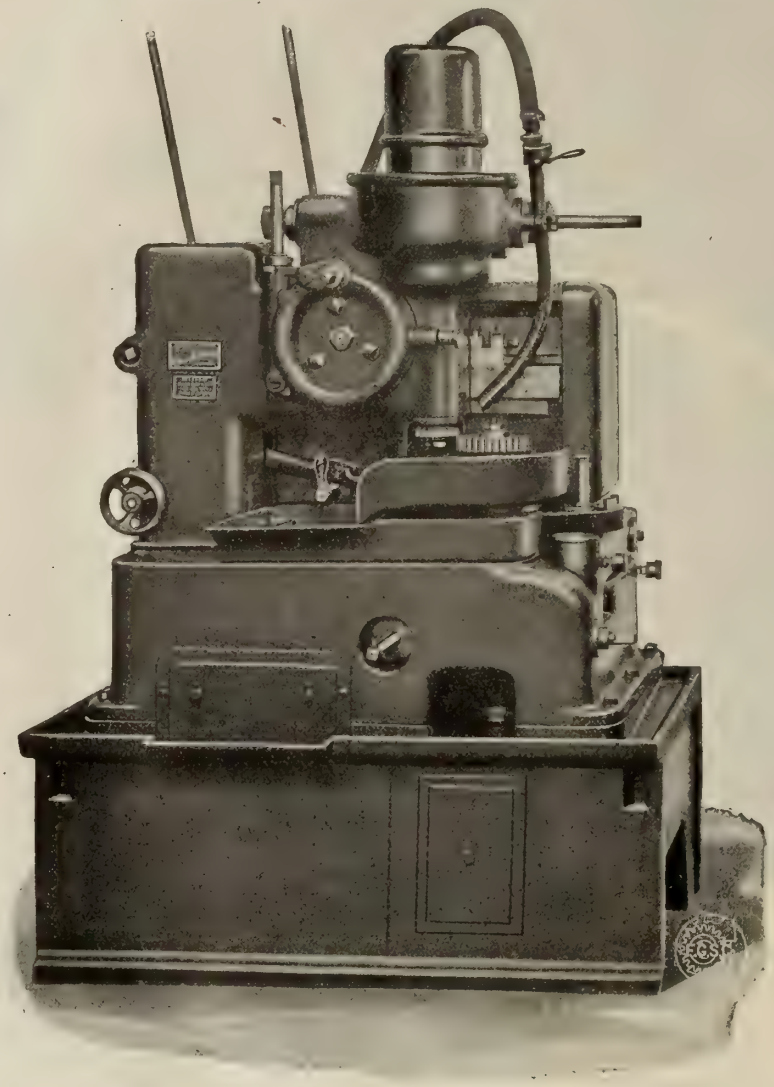
Interior of the shop and to the left the head of one of the pipe threading and cutting machines (together with a typical pipe assembly).

MAKING good five times at once, these Landis pipe threading and cutting machines and pipe and nipple threading machines are producing typical Landis results.

LANDIS PIPE THREADING MACHINES

They are up against the hardest kind of work here in the Shipley Construction and Supply Company plant in Brooklyn. Threading cast, wrought and malleable iron pipe in all sizes, in constant operation and after two years service—the Superintendent says to-day that in his opinion *Landis Machines are far ahead of any other threading machines on the market.*

The variable rake angle of the Landis chaser is responsible for the good threads obtained on the cast, wrought and malleable iron pipe. This feature permits the chaser to be ground to suit the material being threaded. Landis chasers have many other distinctive features which are reasons why Landis stands for good threads, high production and low maintenance cost.



Get complete details now.

CUT GEAR COSTS
WITH THE
New Production Gear Shaper

The new production Gear Shaper, illustrated, has been designed to cut gear costs. It incorporates every feature necessary in a gear cutting machine to obtain this result, and still one of the outstanding features of the Gear Shaper principle—accuracy—has been maintained.
It is designed to cut one gear at a time and at a speed which eclipses all other methods.
All operating levers are at the front of the machine, permitting a number to be bolted together and operated as a unit, one 6 H.P. motor furnishing ample power for 10 machines.
It incorporates to the fullest extent the three principal requirements of production—high speed, accuracy and simplicity of operation.
See illustrated article in all technical magazines.
Send for our booklet, "A New Development in Gear Cutting," which has been prepared for the benefit of Engineers and Production Managers interested in the best gear cutting equipment available.

Write for your copy now.

Just Fill the Magazine and Take Away the Finished Work

HEALD

Style No. 25

For Grinding

Piston Rings
Ball Bearings
Roller Bearings
Collars
Gears, etc.

With the arrival of this new automatic ring grinding machine, the chucking by hand of such work as rings, ball races, collars, washers, gears, etc., will soon be entirely obsolete. Considering that it only requires filling the magazine and taking away the finished product, no concern can compete, using hand operation, for so many human equations enter when the work is handled by this method that the production in a day's time is decidedly low and uncertain compared to that obtained mechanically which gives absolute results at a fixed production day after day.

This machine has been designed and built for large production, all of its units being extremely heavy and rigid with moving parts carefully guarded.

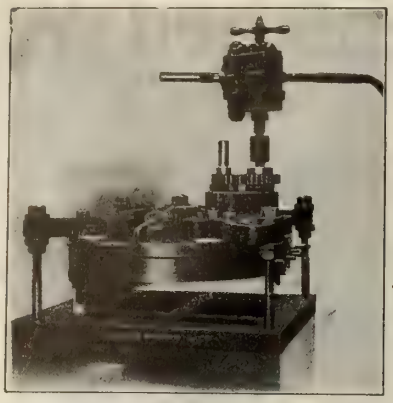
The slide is driven by an extremely simple hydraulic arrangement operated by oil which makes it possible to get any speed from nothing up to the maximum.

The automatic feeding arrangement is made up of a feeding plate with five holes which can be bushed to take rings up to 5″ in diameter. As the plate indexes, a ring is moved from the magazine to the center of the chuck, ground, and then slid off. This arrangement is covered by basic patents owned by this Company and will be protected to the fullest extent.

A two-step cone on the main drive shaft gives two speeds to the wheel which enables the operator to maintain an efficient surface speed throughout the entire life of the wheel.

The chuck spindle housing is absolutely tight which makes it possible to fill it with oil, thus immersing the bearings and gears which drive the chuck spindle.

The diamond which is located on the chuck pan can be readily adjusted to true the wheel to give the desired thickness for the ring.



There are many other unique ideas and units which we will be glad to explain by mail or personally.

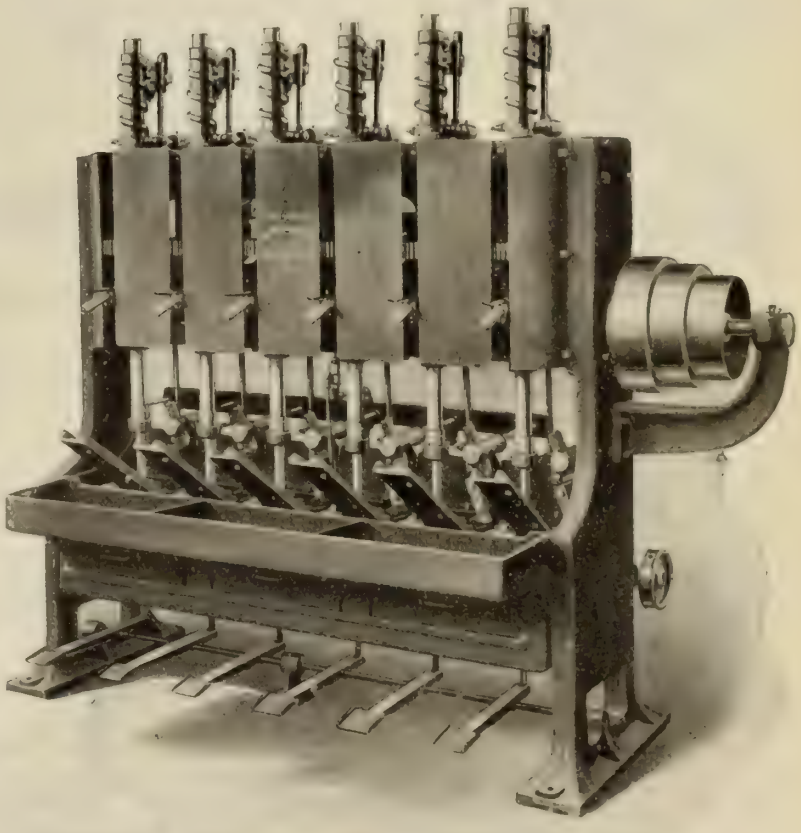
ACME
NUT TAPPING MACHINES



"Our production costs are much too high. We've got to cut down somewhere." —*The Managing Director*

"I unfortunately know that and I've taken it up with the Works Manager." —*The Business Manager*

"I've spoken to the Engineer and he recommends Acme Tapping Machines." —*The Works Manager*

Here's what the Engineer said:
"One plant I know has been averaging 15,000 threaded nuts per nine hour day with Acme Nut Tappers. We need them here."

"I'm with you," says the foreman, "so I think there is satisfaction all round."

Acme Nut Tapping Machines most profitably meet to-day's demand because they are high-speed producers and capable of precision work under the most severe service. According to one leading manufacturer, "We get a spindle speed of 100 r.p.m. which is the limit of the tap endurance on the tough material used." **Wouldn't it interest you to know more?**

MEZZO
Bridging
The Gap

Bridging The Gap

FOR over two decades, every manufacturer who required drills has had a choice between high speed and carbon drills.

It was common knowledge, that in a great number of shops neither drill was entirely satisfactory. Carbon Drills would not give sufficient production and yet these shops were not properly equipped to realize full efficiency from High Speed Drills and consequently could not use these drills except at excessive cost.

We knew that there was a great demand for a drill to meet the requirements of these shops. But with the great press of business during the war, we were unable to turn our attention to this problem.

Since that time, however, we have been experimenting and are now ready to present to the drill users of the Country, a new drill—a "Cleveland" drill—a drill which has been tested and re-tested.

MEZZO

"MEZZO" is a great step forward—the greatest in twenty years.

This drill performs best at speeds and feeds which would soon burn the point of a Carbon Drill, and at these speeds and feeds the drilling capacity of "MEZZO" is astonishing.

Heating the cutting edge of "MEZZO" even to a dark blue color will not draw its temper. In fact "MEZZO" works at its best efficiency this way.

The Gap has been bridged. "MEZZO" gives big production and still is adapted to those shops which can not use High Speed Drills economically. And "MEZZO" sells at a moderate price.

Write for the *"Story of Mezzo."* It is a most interesting little booklet which gives full information on "MEZZO" and its uses.

Surfacing with Norton Grinding Wheels

The only effective way to "machine" a hardened steel plane surface is to grind it. It is also true that other metals, soft steel, cast iron, brass and so forth, may be "machined" cheaper, faster, and to a better degree of finish by grinding than by any other method.

What pieces might you grind? May we help you determine the grinding wheel with:

(1). The abrasive which has the physical characteristics to do the work most efficiently.

(2). The grain size and grade to give maximum production, suitable finish, and capable of giving maximum wheel life.

Whether surfacing wet or dry on a Universal Tool and Cutter grinding machine or on a specially designed plane surface grinding machine, there is a correct Norton grinding wheel for you. Explain your conditions to us—we will select the proper wheel for you.

Points to Watch in Packing Goods for Export

Benefit of Standardizing Type of Boxes—Rules Which Have Proved Useful—Make Cases to Fit Product—Value of Proper Packing and Material List — Avoid Loose Pieces

By J. H. MOORE

THE COMPLETION of a well made product is a natural cause for pride to any factory. Once the nished article reaches the shipping oom, some executives are inclined to ipe their hands of further responsiility, but this department is where the tmost care and vigilance should be xercised. A first class article can rapdly lose its reputation through poor acking. This is especially true if the oods are being boxed for export trade. No matter what the distance, a product hould be packed carefully if there is he slightest danger of damage in any ay. In export shipping, special care required, owing to the length of the urney. The damages caused by poor acking are already well known, and et, year after year, we find goods arving at their destination in poor shape. uckily, all manufacturers are not alike, ith the result that many firms have ade a study of their export packing roblems, reducing it almost to a science. hen this is done we find very litt.e rouble, shipments are prompt, customers are satisfied, business expands, and the firm spending the extra money on careful packing comes out on top. Any extra cost incurred in the shipping room is a wise investment

Work to Rules

Take for example, the Browne and Sharpe Co., Providence, R. I. They are very strict regarding packing, and have four rules to which they strictly adhere.

First, they prevent breakage by so boxing and bracing as to protect against not only ordinary handling, but also rough usage. Seondly, they see that their product is thoroughly protected against rust, and thirdly, they so arrange their packing as to ensure protection against thieving. Last, but not least, they are very particular regarding invoicing and marking, and at all times aim to meet the many varying requirements of countries to which their goods are shipped.

In boxing heavy machinery there are certain principles which shou.d be remembered. First, the platform and skids should be strong enough to support the entire machine, and the platform should be attached to the skids by using heavy spikes toed in on a slant both ways to keep the boards from lifting up when barring.

2. The size of the box should be such that when squared up for length, width, and height, there will be a clearance of at least half an inch.

3. The machine should be so blocked in position that if tipped over the weight will be supported, and all delicate parts protected. All blocking should be placed lengthwise of the grain so as to be less affected by swelling and shrinkage.

4. The top should be sufficiently strong, so as to support any crushing strain which comes on account of the use of a sling in handling when loading on vessels, etc.

5. All small parts, such as wrenches, etc., should be packed in smaller boxes, and attached to the main box in a substantial manner.

Never make the case too spacious for the contents. If you do, any heavy ma-

Every year sees added export trade leaving the port of Montreal.

terial will flop from side to side, and if the parts have delicate portions, or fine adjustments, look out for trouble. In fact pieces such as slides, glass plates, reflectors, etc., should be packed in separate boxes. Excelsior, or the many other forms of packing, are cheap alongside of broken tools, and shattered reputations.

When building a case, make it of sufficiently heavy material. Remember that a box containing a valuable machine of great precision is of no more interest to the laborer or longshoreman handling it, than would be a box of rough building material. Some claim if you mark the case "Handle with Care" that it is assured of careful treatment. As a general rule, little if any attention is paid to such a marking, no matter how prominently it is displayed, or in what language. Use paper between the blocking and painted surfaces in order to avoid, as far as possible, bruising of the paint. Cover all ways of sliding surfaces with waterproof burlap paper, and wrap all shafts in paper of similar nature. Protect all holes, if practical, with wooden plugs, and always place under the top cover a layer of burlap waterproofed paper. Of course, no matter how careful you may be, accidents can happen, but if protective measures are adopted the damage will be reduced to almost nil.

Loose Parts Dangerous

All loose parts which might become unmanageable should be wired in position, or if deemed wise, packed separately. If a machine has a cupboard, it is a good plan to use it for packing small parts. Make sure all finished pieces are flushed or painted with some good nonrust compound or lubricating grease. Brace every part liable to be strained, should the vessel roll, or a longshoreman become careless. Think of the worst not of the best conditions.

Should you have grinding wheels to pack, use lots of sawdust, and on any box where the removal of the cover would cause damage, substitute screws instead of ordinary wire nails. Small boxes, containing miscellaneous parts of a machine, should be so located that they can be removed without disturbing other portions of the packing. Thus, should machines be ordered without certain accessories, the crate, or large box, can remain standard, yet the small box can be eliminated. In other words, make each box a separate unit as far as possible.

Importance Of Checking

Have a careful check placed on all packing work. Make sure that everything is in its place, thus avoiding disappointment and annoyance when the goods arrive at their destination. Standardize the method of making boxes, and have everything so arranged that a new man can, within a very short time, be capable of handling the work. Where a box is liable to stand rough treatment, metal strapping bands help to strengthen it considerably.

The big secret in making export business a success, in the opinion of the Ford-Smith Machine Co., Hamilton, Ont., is to thoroughly understand what you are undertaking. Every country has its own peculiar requirements as to methods of shipping, and these should be carefully studied.

Stencil Plainly

"We make an unfailing practice," says this company, "of stenciling the cases on all four sides, that is, the two sides, and the ends. On every order we get some sort of a simple shipping mark to go by, and in one particular case this took the form of the letters A D S inside of a diamond shaped frame. This shipping mark is easily remembered, and the loaders at the boat can quickly pick it out.

"It pays to spend a bit of thought on how to pack your product. Personally, we devoted considerable study to the matter, with the result that we have our boxes standardized. In these cases every part is well braced. Nothing can rock or chafe on another part with the result that the machine arrives in perfect condition. We paint all polished and machined surfaces with a special rust preventative, and, of course, use waterproof paper inside the case before the outside boards go on.

"Provision has also been made for hoisting hook rings to go through the cases and we do this on all our miller boxes. We have a material list which states all particulars as to size, etc. This means that even a new worker can be sure of preparing a perfect package. We always place band irons around the outside of our export cases."

Without going further into the question of packing, how about the unpacking of a case. Is this important?

Be Careful When Unpacking

To our mind it is, and the more thoroughly a machine is packed, the more care is needed in unpacking, to see that none of the parts are lost.

A case in point. A certain firm wrote a machine tool manufacturer complaining that several parts mentioned on his packing list were missing. After considerable correspondence the parties receiving the machine decided to look at the portions of the case, to make dead sure the missing parts were not there. A search in the boiler room, where the boxing had been burned, disclosed the remnants of the missing parts which had been through the fire. The portions under discussion were shafts packed in a long box, and which were mistaken for blocking timber.

In another case the foreman of a pack-

A British cargo liner—This type is common in almost every port.

ing department traveled quite a distance to prove that the parts which were claimed to be missing had actually been sent. It was treated rather as a joke that he should imagine he could discover the parts after all the search that had been made, but he did just the same, among some packing from another machine.

It pays to have a good packing list at the factory, checked by an inspector who can be depended upon. Then, should complaints come in, you can write the party concerned with confidence, stating he must have overlooked the missing parts while unpacking. In the case of very small pieces, it is sometimes the practice to make the box larger than the size of the parts in order to draw attention to them. The box has even been painted red in some cases in order to attract attention. The more a machine is dismantled in shipping, the greater the danger of parts being lost, or of difficulty in assembling.

Always get proper information as to the conditions and requirements of the country to which you are shipping. By doing so you will avoid both expense and delay. In packing goods for export, remember the long and rough journey ahead of them. If you were going on a journey you would make all due preparations to arrive at your destination in good condition. How much more so then should you see to it that your product, which is after all a part of you, should be so packed as to arrive in perfect condition.

The Buyers' Wishes Should be Carried Out

Based on an interview with F. W. FIELD, British Trade Commissioner in Ontario.

"PACKING GOODS for export is, as experienced manufacturers know, one of the most important factors in the conduct of successful export trade." In this way F. W. Field, British Trade Commissioner in Ontario, summed up the matter during an interview with Canadian Machinery.

"I believe," he continued, "that exporters may with advantage use to a greater extent than at present, the facilities offered them by trade commissioners and other government officers, whose principal duties in the various markets, is to render assistance to manufacturers who desire to cultivate trade in foreign markets. Much useful information as to packing is available in their offices and other data desired can be secured upon application.

"I was told some months ago, of a Canadian government trade commissioner in another Dominion, who made a practice of watching shipments from Canada unloaded at his port, particularly with a view to noting the condition of packages on arrival. In one instance, for example, he found a shipment from Toronto had arrived in broken packages, the damage to the goods being serious. He made a full report to the Toronto firm suggesting certain changes in their packing methods in order to meet the requirements of the ocean voyage and the general handling of their goods. These suggestions were adopted, thus ensuring the receipt by buyers abroad of merchandise in good condition and preventing disputes and claims for damage.

Avoid Damaged Goods

"Complaints are sometimes heard that United Kingdom manufacturers charge for their packages, but it should be remembered that British exported goods, as a general rule, are among the best packed in the world. It is far better to pay a little more for adequate packing, than to have damaged goods. It is sometimes said that certain foreign firms do not charge for their packing. Generally, however, a packing charge is included in their price. British firms frequently state their packing charge in addition to the price of the goods.

"I have seen foreign goods landed in Canada, the manufacturers having stated that no packing charge is being made. The recipients, however, have often wished, upon viewing the damaged condition in which the goods have arrived, that a packing charge had been made and the goods had been properly packed for export.

"During the past winter, I made an official tour of five months' duration, to many of the principal industrial centres of the United Kingdom. A number of plants were visited where I saw the packing of British goods. Considerable care is given to packing by manufacturers and shippers there. This remark applies to both small packages for display in wholesale and retail establishments, and to packages in a large way for export trade. Motor trucks were being packed at plants I visited in a manner which would satisfy every possible demand of ocean and rail journey. Overseas importers may rest assured that the experience of reputable firms in the United Kingdom in packing will guarantee the arrival of goods in excellent condition, and that condition is a great asset to an exporter.

Please The Buyer

"The desires of local importers as to the methods of packing goods should be carried out as far as possible. A chinaware importer, for example, may wish many of the dinner sets purchased to be twelve sets to a withy crate, each set being packed separately, so that the outer crate may be broken and the sets shipped individually from the local establishment without repacking. His wishes should be carried out, otherwise another firm may secure the business.

"Considerable pilferage from packages continues. It is a matter of opinion as to where this happens, but in some cases it is thought to have occurred on board ship. It has been suggested that manufacturers of goods which attract pilferers, who gradually learn the character of merchandise contained in cases of certain markings, should periodically change their markings. Whether the possible saving justifies the trouble involved, or whether other steps can be taken to reduce the losses from this cause, is for manufacturers and shippers to determine.

"The packing and shipping room is one of the most important branches of the exporter's business Upon the extent of the care taken in that room by those responsible for packing the manufacturers goods for foreign markets, depends very largely the success in building up his export trade."

BENEFIT OF CAREFUL PACKING

Mr. Norman Holland of the Holland Varnish Co., Montreal, made a very interesting and instructive statement at a recent meeting of the Canadian Railway Club, when the subject of freight claims was under discussion. Mr. Holland states that his firm, some twelve years ago, decided to pack all their outgoing shipments in the best kind of containers. Their package and box costs are from 60% to 75% higher than most firms shipping similar lines, but the result is that for twelve years they have never had an outgoing freight claim. They further inaugurated the idea of refusing to purchase from firms that did not use the highest grade of packages, the result in this case being that their claims arising from incoming freight have been steadily decreasing until in 1919 they had only one claim. In 1920 and 1921 they had none whatever. These statements may carry more weight when it is understood that the volume of the business handled by this firm has been steadily increasing, until in 1921 it amounted to over one and one quarter million dollars.

MOVABLE HIGHWAY BRIDGES

It is not generally known that fifty movable highway bridges are maintained by the city of Chicago, the different types being as follows: Twenty-four trunnion bascule bridges, twelve centre bearing swing bridges, twelve rolling lift bascule bridges, one vertical lift bridge and one pontoon bridge. Of the trunnion bascule bridges, twenty-two are of the type developed by the city and the others are of the Strauss and Page & Schnable types.

Rapid Holding and Releasing of Gear Blanks

Eliminate Slow Removal of Clamps—Give Cutters and Tools Sufficient Clearance—Holding With Spring Collets of External or Internal Type—Use of the Draw-Back Rod

By FRED HORNER

AMONGST the items that go to make for increased production in gear-cutting is that of the rapid fixing and release of the blanks. The smaller the amount of cutting done per unit, or the greater the tooling is speeded up, so also must the fixing be hastened in order to gain the full advantages from the scheme. Any slow and laborious undoing of bolts, screws, removal of clamps, and the inevitable wiping and cleaning upon their replacement has to be eliminated, and is

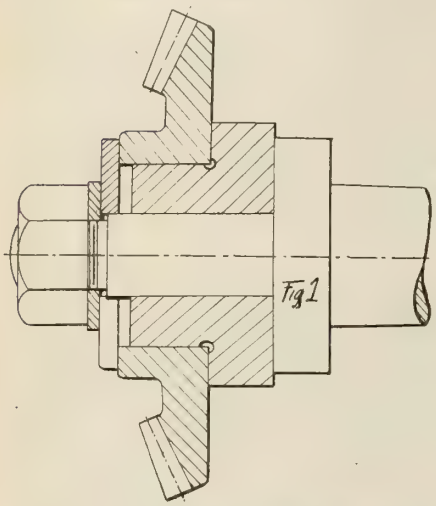

Fig. 1 — Slip washer on ordinary arbor.

only permissible in the case of gears difficult to clamp, or which consume a comparattvery long period in the cutting.

Very often the modified methods introduced with a view to time saving also add to convenience in other ways, such as affording better clearance for the cutters or tools; frequently also, the expenditure of muscular effort is reduced materially, and less damage is done to the holding parts. This latter means a longer life and state of accuracy, ensuring better gears, and less time wasted in rectifying damaged arbors, nuts, threads, washers and bushings. The following notes relate to diverse methods applied to differently-shaped blanks.

The nut and washer mode of holding a blank on a plain arbor not the quickest device, but is of course commonly adopted. A slip washer fitment is not practical unless the blank bore is large enough to pass over a good-sized nut, as in Fig. 1, and then the slotted washer admits of instant placement and removal without troubling to remove the nut and washer. On large ring fixtures for holding gears with a continuous circular clamp, or several oblong ones clearance openings in the one instance, Fig. 2, or slots of sufficient length in the other, Fig. 3, afford freedom for a part rotation to lift the ring clamp off, or to slide the oblong one backwards.

Application of Slip Washer

The most effective application of the slip washer in the case of small diameter gears occurs in collaboration with a handwheel operated drawback mechanism. The projection at the nose of the gear is thus reduced to the minimum, while a powerful tightening effort proceeds from a strong screw located elsewhere. In the Gleason bevel-gear machines, for example, a handwheel with pilot projections is situated at the tail of the spindle, and turns a nut encircling a screw that is prolonged into a drawback plunger. The end of this has a recess turned to receive the slip washer, and so the blank is firmly held, Fig. 4 A. Three variations are also shown, including the flange rear washer B, to square the recessed blank by its back surface, a cone slip-washer C for a small pinion, and a screw nut D for a very tiny size. Although a nut is

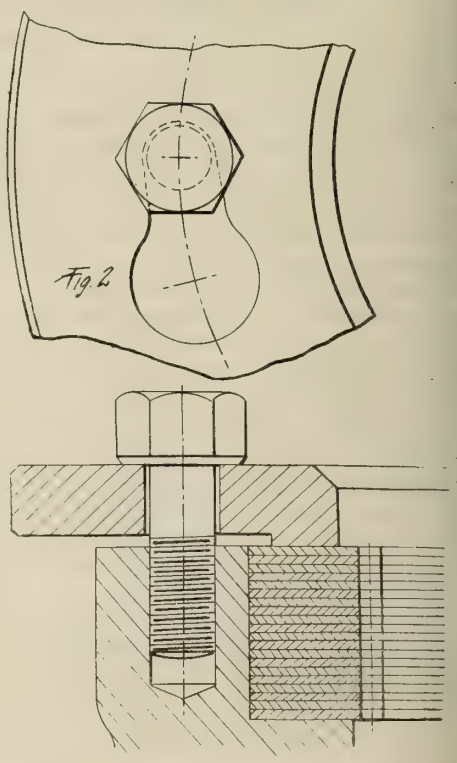

Fig. 2.—Bolt clearance holes in clamping ring.

employed here, it is useless for binding purposes, the tightening being accomplished as before by the pull-back rod.

A considerable proportion of holding is done by spring collets of internal

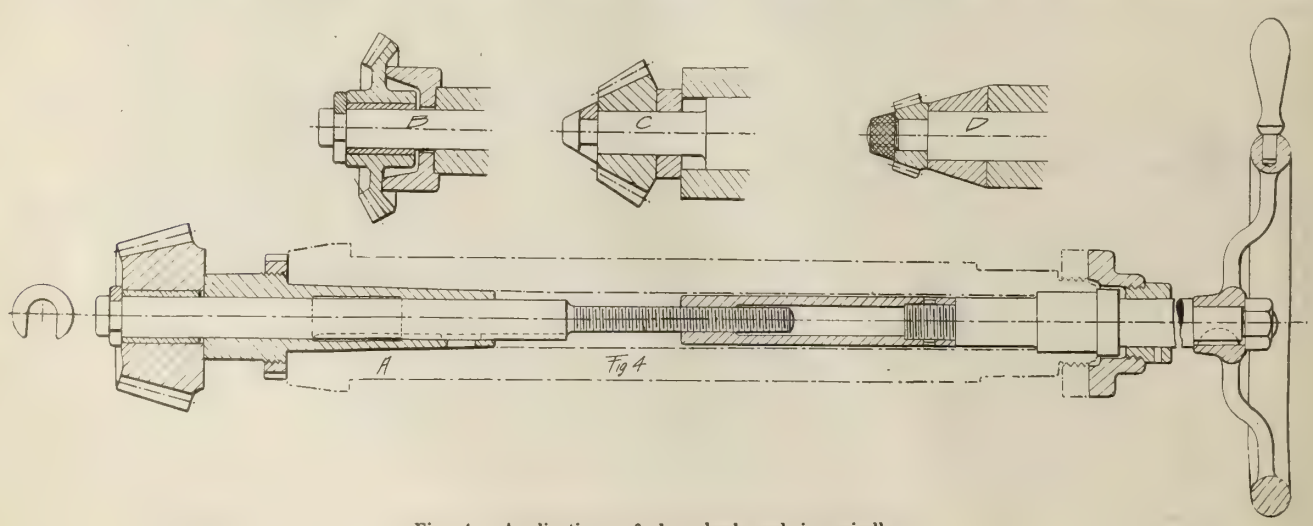

Fig. 4 — Applications of draw-back rod in spindle.

or external type. These, if made and used properly, have the advantage of concentric holding, and a better grip is obtained than that from an arbor or a hole which is not a correct fit for the gear aperture, or its stem as the case may be. Some of the Brown & Sharpe gear cutters are provided with expansion arbors incorporated into the construction of the spindle, after the manner of Fig. 5, and turning the handwheel forces the taper end of the arbor into the split bushing A, and expands the latter in the bore of the blank.

Two other devices for producing expansion, the one with a draw-back rod, Fig. 6, and the other with a nut from the front, Fig. 7, show alternative possibilities, the second idea being applicable to any loose arbor.

Fig. 8 illustrates a lay-out for producing a powerful expansive effect from means located behind the gear, so leaving the front clear for the extension of the arbor into a supporting stem. A similar principle, but applied to gripping the stem end of a gear, is represented by Fig. 9. Accurate centering and a powerful clamping grip are ensured. If a draw-back rod is passed through the spindle, or arbor, a simple fitting like Fig. 10 becomes possible.

Certain machines used for cutting pinions integral with their shafts or for milling worms similarly made, embody in their spindle arrangements a strong collet chuck, with draw-back or push-rod or tube to chuck the shafts accurately. An interesting design of a special character may be noted in this connection, from a worm miller constructed by Messrs. David Brown & Sons, Ltd., Huddersfield (England). One end of the worm blank is gripped by the collet chuck, while the other end runs in a roller steady.

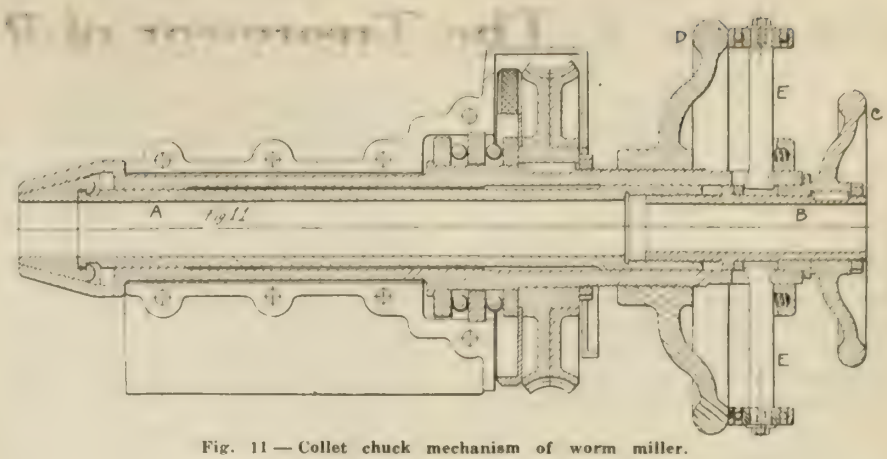

Fig. 11 — Collet chuck mechanism of worm miller.

The collet is contracted by end movement of the tube A, forced along by the rotation of the operating sleeve B, turned by handwheel C. Then a great increase of pressure is given by turning wheel D, which screws its way along and actuates two toggle levers E, E, the lower ends of which press against a hardened steel collar which transmits the pressure to the sleeve B. Ball collars on the ends of the toggle levers provide for the tightening taking place with the least friction.

To a moderate extent the principle of simultaneous tightening has been utilised, that is, several spindles contain draw-back rods or contractile collet de-

(Continued on page 46)

The Treatment of Refined Oil Distillate

Removing Wax by Cooling—Treating Lubricating Oils—Making Pitches and Asphalts—Production of Still Gas—Storage—Protection Against Fire—Machine Equipment Necessary

By C. D. DEAN, A.M.E.I.C.

IN the Jan. 26 issue, we discussed the selection of refinery site, style of boiler plant used, and power requirements. Then came the first distillation process, the cooling of oils, treatment of distillates, and so on. Next we will proceed to go into further treatment necessary.

Treatment of Refined Oil

The treating of refined oil distillate is similar to that for naphthas, except that this is always batch in a loose top cone bottom agitator. The reason for this is that the oil has some viscosity and it is difficult to get an intimate mix of chemicals and oil without violent agitation. This agitation is secured either by blowing with air or by circulating through a pump. Blowing with air means large losses; circulation with a pump means longer time and therefore large investment, but at the present time, both systems are in use. If, however, the oil contains large quantities of sulphur, blowing must be resorted to in order to get efficient chemical action.

After treatment and neutralization, the kerosene distillate is charged continuously to a battery of re-run stills which are, as in the case of crude stills, of about 1000 barrels capacity each using bottom steam. With these stills use is made of vapour heat exchangers and towers, as well as oil heat exchangers and coolers for the residual bottoms. The condensation in the vapour heat exchanger and the tower is removed through separate cooling coils, while the vapours passing the tower are conducted into a worm. From these stills is taken a gasoline cut and refined oil as well as what is known as a re-run cut for a retreatment and re-distillation and the bottoms go to fuel oil.

There are many specifications for gasoline and refined oil, but in operating in the refinery the former is run for boling points, while the latter is run for flash and viscosity which in a measure are imperfectly related.

The lubricating distillate contains the waxes or at least most of them, and before it is ready for finishing and treating, this wax must be removed. Present day practice involves the cooling by refrigeration of the whole distillate to between 32° F. and 0° F. and forcing the distillate under about 1000 pounds per square inch through filter presses where the wax crystallizes out and allows the oil to drip through. In cooling the distillate, it is fed through chilling machines, which are a series of long pipes, in which screw conveyors work to prevent the wax from adhering, and around which the brine is circulated. It requires a press for every 200 to 250 barrels of distillate and about 25 tons of refrigeration per press. After the press is full of wax, the filter plates are loosened and the slack wax drops into a hopper with a conveyor in the bottom, where it is broken up into small blocks and discharged into rundown tanks. In the rundown tanks the wax is melted and heated to quite a high temperature when it is pumped to the wax sweaters.

Slack Wax

The slack wax contains about 50 per cent of its volume as oil, which must be removed before the wax is ready for treating and finishing into commercial articles. Wax sweaters consist of two sets each, consisting of a series, usually 12 to 24 shallow pans, one above the other carried on a frame work and enclosed within a brick or concrete building. The building has no windows, but both ends are almost completely doors, and the roof has ample adjustable ventilating openings, while the sidewalls are covered with steam coils.

In each pan is installed a closed coil on top of which is a screen of about ¼ inch mesh, although coarse sand is sometimes used. Each pan is filled with cold water up to the screen, and on top of this is pumped the hot slack wax, after which cold water is circulated through the coils if necessary to cool and solidify the wax. After the wax has become solid enough the water is run from each pan to the sewers and the doors and ventilators are shut, after which the steam is turned on in the building which heats the air and allows the wax to soften sufficiently to allow the entrained oil to filter through to a pipe line that carries it to the pressed oil tank where the oil, which escaped from the presses when the wax was being pressed out, is stored preparatory to being transferred for further treatment.

After the oil has been sweated out steam is turned on in the coils within the pans which melts the wax and allows it to run down a separate line into what is known as a rundown tank building, which is plentifully supplied with steam coils. From this building the wax is fed to the wax treating plant, where it is filtered through Florida clay to eliminate the colouring matter and is then sent to the candle works where it is moulded into candles and other shapes for consumption.

Reducing Department

The oil from the wax presses is delivered to the reducing department, where it is distilled in reducing stills either continuously or batch. These stills are never run down to coke and all the overhead distillates are closely fractioned into the various grades of lubricating stocks. The oils all carry considerable viscosity and they are allowed to issue quite warm from the ends of the worms, from 125° F. on up, depending on the viscosity. The bottom is the very high viscosity oils which at temperatures little below boiling temperature would flow very sluggishly, and it is termed a bottom product. As cracking, which destroys viscosity, is to be eliminated, great quantities of steam are used, about one pound for each pound of oil overhead, which must be disposed of and in order not to make it necessary to install too large a worm the steam is withdrawn from the worm after the oil has become liquid by a light suction induced by a jet of water.

When the stills run continuously, an effort is made to conserve heat by creating a suction through an exchanger, where the steam gives up some of its heat to the ingoing charge.

The lubricating distillates, including the bottoms, are transferred to the treating plant where they are treated to remove objectionable matters of various kinds which are due to the insaturated compounds.

The treating is done in agitators which are equipped with closed coils running up and down adjoining the interior of the shell vertically. After charging, the steam is turned on and the batch is heated up to reduce viscosity and the acid dumped in successive doses, while the whole is agitated violently for some hours by an excess of air. The acid heat and the heat from the coils serves to allow the sludge to settle out, when it is drawn from the cone bottom of the agitator into either an acid coke pit or cooking kettle.

Treatment of lubricating oils sometimes necessitates as much as 50 pounds of acid per barrel of oil and there is a great deal of sulphuric acid left in the sludge and in a sludge coke pit; this is allowed to fester and drop out as coke, which can readily be handled and burned. With a cooking kettle, however, live steam is turned in the mass which separates the uncombined acid and the coke and this uncombined acid is pumped to the acid restoring plant and the coke, which is much less in amount in this case, can be handled and burned.

The treated oil in the agitator is now transferred to a wash tank, which is about double the capacity of the agitator, and which is jacketed and equipped with both open and closed steam coils. Here the oil is thoroughly washed with hot water about 180 degrees F. and as the oil has been heavily treated, larger quantities must be used. After treating and washing the oil is neutralized

with a soda solution and again washed with large quantities of hot water. The batch is then left in the wash tank and is maintained at a high temperature by the steam coils to permit the water to settle to the bottom. After all the water has settled out that can be eliminated in this way, the oil is transferred to a bleacher which is a tank, contained within a building, and in which is a large steam coil as well as air blowing coils. In the bleacher the oils are blown bright, i.e. the moisture is all eliminated, and are then transferred to the stock tanks, either for shipment or for filtering through clay to remove soapy substances that attract moisture and that in certain services would be deleterious.

Pitches and Paving Asphalts

One of the modern developments in the art of refining, which is growing enormously, is the production of pitches and paving asphalts from asphaltic base crudes, which in America come from California, Texas or Mexico.

This distillation is conducted batch in 1000 barrel stills, the condensers of which have large worm capacity. For certain crudes comparatively low in asphalt or pitch content, the stills are equipped with one or more towers for fractionation, but when the asphalt content is comparatively high these are not used. Mexican crude is the only one that the writer knows of that is used in Canada for the production of asphalts.

The various light oils come over successively and depending on their boiling points comparatively close fractionation can be arranged in the tail house on the basis of gravities. The present practice is to produce asphalts as a bottom product, that is they are not driven overhead, on account of the high temperature necessary to do this. The steam serves the purpose of preventing the rise of temperature and thereby prevents the cracking of the bottoms, and asphalts can be produced that will have a minimum of carbon content.

The steam is drawn from the worms beyond the point where the oil has condensed and is condensed with a water jet in a sealed chamber from which the still gas escaping with the steam is pulled by exhausters and burned beneath the stills. In order to cheapen the cost of operation, insofar as the use of bottom steam is concerned, some California refineries use vacuum stills operating at from 24 to 26 inches of vacuum, and in addition introduce small quantities of steam which if properly distributed facilitates circulation and thereby prevents local heating.

High melting asphalts are produced by blowing air through the bottom, as it lies in the still and a slow fire is maintained beneath. It is claimed that the effect of the air is to oxidize some of the hydrogen in the chemical structure of the pitches producing the higher in the series with consequent raising of the melting point and the other physical characteristics that go with this. It may be mentioned that about 500 cubic feet of free air is required per minute per still for oxidizing purposes.

Distillation under Pressure

In the early days of petroleum refining the effort was made to produce all the refined oil, fuel and lubricating stocks that the crude would yield and waste the light fractions, now in such demand, and a good crude was considered to be one in which the percentage of fractions lighter than those permissible in refined oil was low. The development of the motor car, truck and tractor has radically changed the situation and crude oils are now valued, very largely on the basis of their gasoline and lubricating oil content. It was quite natural to expect that with a knowledge of the fact that crude oil can be cracked at atmospheric pressures in a coking still, an effort would be made to see what advantage would lie with distillation under pressure.

Several patents in this direction were secured very early when the demand for gasoline showed evidence of exceeding the supply, and there are a few that are being commercially used on a large scale by big refineries in the United States and Canada. There is an immeasurable host of patents of this kind appearing every month, but they are mostly mechanical deviations from the existing apparatus and depend for success on the same principles on which all are based.

The first principle is that oils suffer a redistribution of molecular structure when raised to their critical temperatures and the heavier fractions have critical temperatures lower than those for the lighter fractions.

The second principle is that as pressure is made use of to get the higher temperatures it is necessary to produce a fixed gas as well as condensible vapours in the still in order to hold pressure.

Probably the most successful apparatus in use is that covered by the Burton patents now owned by the Standard Oil Co. (of Indiana) and licensed to various companies in the United States and Canada. The stills use a gas or fuel oil of 30 to 35 gravity, as charging stock which contains comparatively heavy fractions, having little or no lubricating properties and which would ordinarily reach the market as fuel oils. They are charged batch and run semi-continuously at about 96 pounds gauge pressure and have a capacity varying between one and two hundred barrels each per day. Approximately 50 per cent. of 50 gravity distillate is taken off overhead and the bottoms are about 22 to 26 gravity. There is a loss of about 3-½ per cent. in operating which is nearly all gas. These stills sometimes have quite complicated overhead fractionating equipment to knock down for recracking the heavier vapors as there is a rise in still temperature occurs of about 100 degrees F. during a run as the gravity of the bottom increases.

The fuel consumption is about 1-8 of the charge if liquid fuel and the fixed gas produced is around seventy-five cubic feet under standard conditions per barrel charged. The still temperatures vary from about 640 degrees to 740 F. and the flue temperatures are around 1200 degrees F. The latest practice is to install steam superheaters in the flues to supply superheated steam to the various continuous and reducing stills using bottom steam.

The distillate is treated either continuously or batch, similar to the method of finishing crude naphtha and is then distilled continuously either in fire stills or steam stills and yields gasoline, refined oil and a residual bottom which is gas oil.

The general refinery production of still gas, which will average probably about a hundred thousand feet per 1000 barrels per day, is usually burned in the refinery although instances in the United States are not rare where it is sold to gas companies direct as enrichment for water, gas, etc. In refineries a very elaborate system of exhausters and gas lines is installed to dispose of it and when the production is large with wide fluctuations in the rates of production, as sometimes occurs, gasometers are used to prevent loss.

The still gas is usually found to have a heating value from 1000 B. T. U.'s per cubic foot to as high as 1800 B. T. U's per cubic foot, depending on the amount of gasoline vapour carried. Modern practice now calls for absorbers to extract the vapours from the gas which is usually done by forcing the gas after cooling, under low pressure through towers in which a menstruum of gas oil or any other similar heavy oil—the initial boiling point of which is considerably higher than the final boiling point of the absorbed naphtha can be—is trickling. It is ordinarily found that the menstruum will absorb about 10 to 11 per cent of its volume as naphtha and a gas that will yield one Imperial gallon per 1000 cubic feet is considered to pay for the extraction. The menstruum with entrapped naphtha is steam stilled under about 15 pound gauge pressure and the recovered naphtha, after treatment, is mixed with the current production of naphtha. On steam stilling, it is found that a loss of about 5 per cent. of the volume of the menstruum occurs, i.e. this amount goes overhead with the naphtha.

Storage

Practically everything including waxes and asphalts—but of course not coke—is stored in tankage and handled by pumping. The tankage is all steel and varies in size from 5 ft. diameter by 10 ft. high, having a capcity of 35 barrels to 120 ft. diameter by 40 ft. high, having a capacity of 80,000 barrels.

The tanks are designed for a stress of 20,000 pounds per square inch on the net area of the shell, when full of water, but no plate in the shell or bottom is less than ¼ inch thick, generally speaking.

the bottom is made of 3-8 inch steel and the roof plates of 3-16 inch material. The roof is designed to carry a wind and snow of 30 pounds per square foot and while the practice of a few years ago was to install truss roofs quite extensively, the present practice is to use I beam supports, bolted at one end and free to slide on the other to take care of tank distortion, due to settlement of the foundation or varying elongation of the materials with differing oil heights.

Tanks varying in capacity from 20,000 barrels to 80,000 barrels weigh about 9 pounds per barrel, while for tanks from 10,000 barrels to 20,000 barrels the weight of steel per barrel is about 10-¼ pounds and for tanks from 5,000 to 10,000 barrels the weight is about 12-½ pounds per barrel.

The space occupied per tank is quite variable, but very roughly follows the plan of allowing one square foot of ground per barrel capacity. The deviations from this rule are frequent however, depending on the shape of the tank lot and local regulations, if there are any. As far as possible, for light products, i.e. gasoline, refined oil, fuel oil and crude, the tanks are surrounded by dykes—built high enough to hold the contents of the tank should disaster occur, but there is a rule restricting the height of the dykes to 6 feet, and it is adhered to quite religiously on account of the need for accessibility for hose reels, etc.

For certain heavy products, such as heavy crude oils, fuel oils, lubricating oils, waxes and asphalts, the tanks are equipped with very elaborate heating coils, the surface of which is designed on the basis of the highest expected pumping rate, and in addition, certain lubricating tanks and all wax and asphalt tanks are jacketed with four inch hollow tile jackets to conserve heat and assist in maintaining high temperature. Every tank is equipped with two or more water draw-offs, in the shell near the bottom, which are arranged so as to remain full of oil after the water has been withdrawn from the tank. In tanks 25 ft. in diameter and larger, two manholes are provided, one on the roof and one on the shell near the bottom.

The oil lines are connected through the shell either at the top or the bottom. The top connection is favored by some people, as line breakage does not involve the loss of the contents. It does, however, mean a continuous maximum pumping head and the bottom connection on this account is generally used. To safe-guard as much as possible against loss from line breakage, the line inside the tank is on a swing either by using a specially constructed valve or by using two wells so that the entrance of the pipe can be raised above the oil level.

The oil lines are all screwed steel pipe and are made large enough to give a total head for a refinery on level ground of from 65 to 75 ft., i.e. when centrifugal pumps are used, but for asphalts, waxes, etc. the pumping heads vary, although initial starting pressures greater than 100 lbs. per square inch are not favored. In general for all important inter-refinery process pumping, no line is made less than 6 inch. Process pumps, motor driven, are either centrifugal driven by constant speed motors, or triplex single or double acting, or some of the patented positive displacement pumps driven by variable speed motors. In pump-houses, which are located in carefully selected locations and are as few in number as possible, the pumps and motors are separated by brick walls as an additional protection against fire. For certain purposes, such as pumping waxes and asphalts, etc., no motor driven apparatus can be used, because the power required at starting is several times that required after the volume of oil in the line gets moving, and it is usual to put in a high ratio duplex steam pump for this work, as the exhaust steam need not be wasted.

Fire Protection

Fire protection is an important consideration in an oil refinery and large expenditures are made to provide fire fighting facilities on an elaborate scale. All tanks are equipped with 2 in. steam fire lines, which enter in two places on a diameter near the top and which during thunder storms are opened. If steam enters a tank and displaces the air, the risk of fire is nil, but after an explosion if the roof blows off, and it nearly always does, steam is comparatively useless. During the past five years a new system of fighting oil fires has been developed known as chemical foam and there are three commercial foam formulas in use now.

The foams are mixed right at the tank in a mixing chamber either within or without and when discharged on the surface of burning oil act as a blanket. The protection required per tank is difficult to estimate and is usually based on judgment. A conservative figure is that about three feet of foam per tank will be needed which is equivalent to about three gallons of solutions per square foot.

Current practice does not call for the installation of foam storage, totalling the whole risk, and it is customary to provide storage for, roughly, 10 per cent. of the tank risk. The foam making solutions are kept in separate tanks until required. In all the foam making formulas, the acid solution consists principally of 10½ to 12 per cent. by weight of aluminum sulphate and 85½ to 89 per cent. of water. The soda solution consists of about 8 per cent. of sodium bicarbonate and 89 to 91½ per cent. of water. These produce the carbon dioxide and the other ingredients to produce the bubble for containing the gas, differ.

In the first one, glue, glucose and arsenous oxide are added to the soda solution. In the second, foam powdered extract of licorice is added to the acid solution, while in the third foamite is added to the soda solution. The first two are not used much for new installations, as the bubble material deteriorates rapidly. In all cases, the expansion by mixing is about eight to one when fresh solutions are used, but ordinarilly refinery storage solutions will give an increase of about 6½ to 1.

To cover a refinery risk means quite an extensive network of lines, as well as powerful pumping equipment, and it may be noted that foam hydrants are located at strategic points to permit the use of foam an other risks besides tanks.

Probably the most expensive fire fighting apparatus consists of the usual water protection. This consists of the well known hub and spigot pipe which in refinery work is all class "C" and powerful pumping equipment with boosters wherever necessary. It is the aim to provide for at least 12 standard 2½ inch hose at the farthest point in the fire lines. The use of water in oil fires is simply to keep surrounding apparatus and tanks, buildings, etc. cool during the progress of a fire to prevent, insofar as this means will, the widening of the fire area.

Railway Trackage and Wharf Facilities

The amount of trackage required at a refinery varies considerably and depends on the percentage of the crude and finished products that will be moved by rail, as well as the amount of tank car storage space desired for seasonal variations in the movement of finished products. A rough figure of trackage requirements is about a half mile per 1000 barrels of crude daily, but for plants located on water it will be very much less than this.

Tank cars for use in the transportation of oil are built in accordance with the American Railway Association's specifications for carrying inflammable liquids, whose vapour pressure does not exceed 10 gauge at 100 degrees F. If however casinghead naphtha is to be moved, Class IV tank cars must be used.

Wharfage facilities for plants erected on navigable waters, are, as far as possible, pile structures with deep water surface, approximately 400 ft. long and arranged for a boat draft of 20 feet in fresh waters and 30 feet at low tide in sea waters.

The deck loading is figured at about 400 pounds per square foot. For certain sea locations, particularly in South America loading and discharge of steamers is done through undersea lines, which sometimes are laid a mile out before sufficient depth of water for boat draft is reached. The end of the pipe line is either a hose supported on an anchored float or a small deck protected by pile dolphins. Such lines have a life of about four years.

Repair Shop Equipment

As mentioned previously, a very large part of the expense of refinery operation is due to the excessive repair work necessitated by the severe punishment that distilling

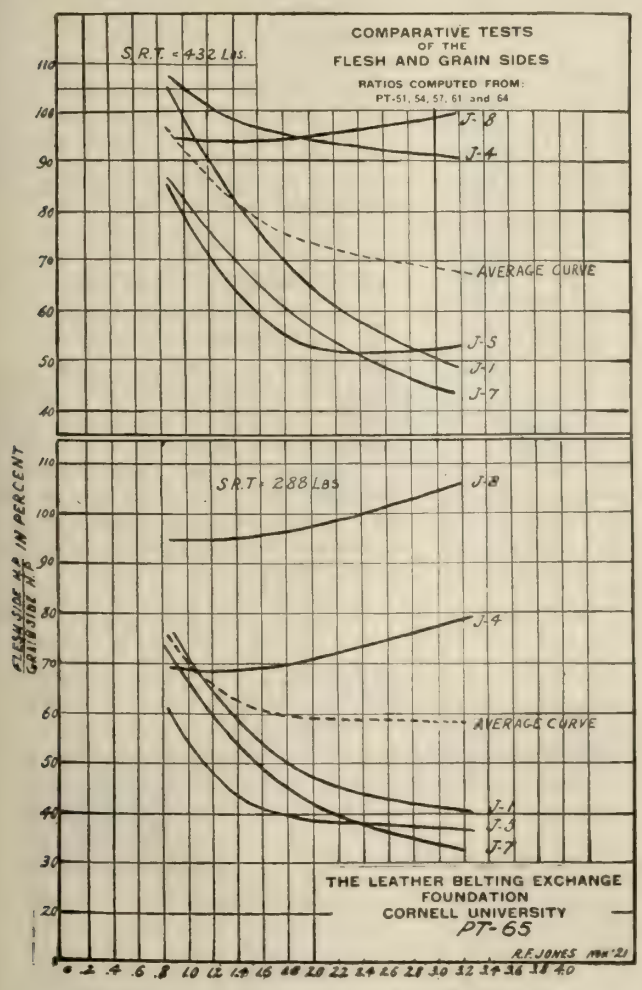
Grain or Flesh Side for Leather Belting?

Tests Made to Ascertain Transmission Efficiency—Horse Power Reading Taken While Running—Stretch May be Annoyance But It Protects Both Belt and Machine—Grain Side Favored

THE QUESTION of whether a leather belt should be run with the grain or flesh side next to the pulley has been, until quite recently, in the same category as the old saw: "How old is Ann?" From the time when leather belts were first used for power transmission until the present, men have argued the matter pro and con without having any definite facts upon which to base their opinions or any more really concrete evidence than that of individual observation. The very natural result has been as many opinions on the matter as there were men to voice them.



It appeared to some men that a closer contact with the pulley could be had by putting the grain side of the belt next to it. Others have contended with equal conviction that the flesh side, being tougher, was better able to withstand friction. And still others have gone into the realm of metaphysics for their argument, maintaining stoutly that a wise Providence had placed the flesh side of leather next to the animal deliberately and it was not for man to reverse that order on a pulley. But speculation on the matter is at an end; scientific experimental evidence has been obtained to settle the controversy once for all.

During the latter part of the past summer, tests of the capacity of the grain and flesh sides of leather belts were begun by the Leather Belting Exchange in its research laboratory at Cornell University. They were under the direction of Mr. R. F. Jones, director of the laboratory. Covering a period of more than two months' continuous tests were run on the testing apparatus belonging to the exchange, which is being operated under the supervision of Cornell University, using five 4-inch single belts, 30 feet long, of different manufacture. They weighed from 16 to 18 ounces. Every effort was made throughout the tests to standardize conditions and to reduce the probable error to a minimum, and this unquestionably was accomplished. All five belts were run long enough previous to the experiments to have been thoroughly "run-in," and had reached a condition of constant capacity when the records were taken.

Method of Testing

The method of procedure was to take horsepower readings from the belts first when running on the grain sides, and then when running on the flesh, the power being gradually increased until about 4 per cent. slip had been reached.

In considering the results, it must be remembered that a leather belt is at its lowest point of capacity when new, largely because of the elasticity of the leather and the newness of its surface. Leather belts are well stretched in the process of manufacture, so that when the belt is put on the pulley there may be as little stretch as possible consistent with thorough lubrication and retaining the natural life or elasticity, which is such a valuable property of the leather belt. When a new leather belt is placed on the pulleys, however tightly, it will elongate under load. But after the tension of the load has been removed it returns very nearly to its original

This chart shows curves computed from different ratios.

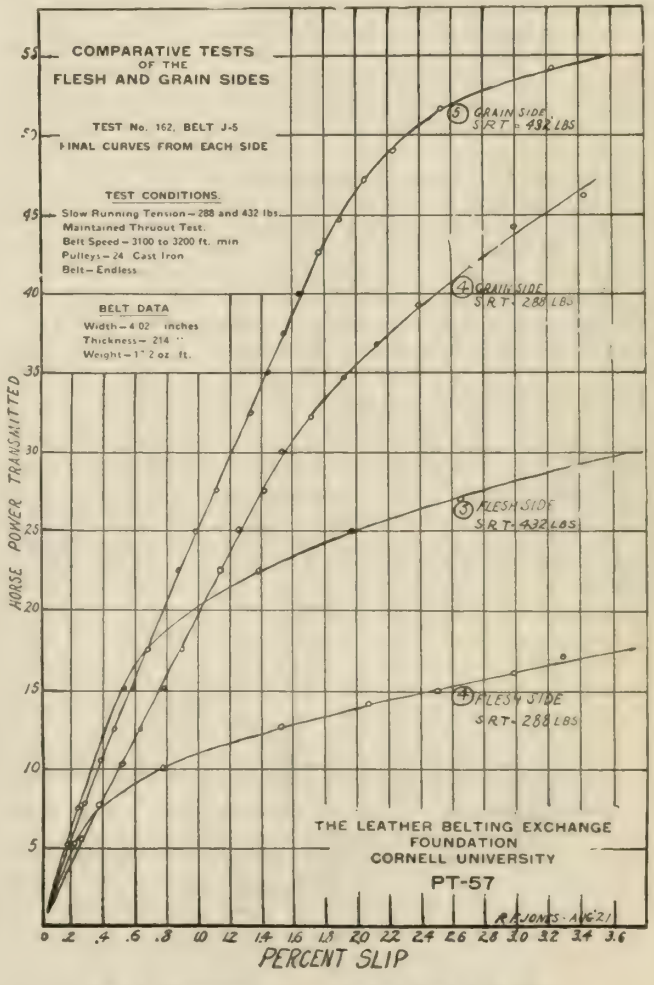


Fig. 1.—Showing the final curves from each side.

length. This stretch is an annoyance when installing a new belt, but it is of the nature of a safety valve, protecting both belt and machinery.

The newness of the surface, however, makes it necessary to "run in" the belt when testing it. That is, to run it for a sufficient time to permit the belt to attain its maximum capacity in transmission. As an illustration, one belt under test at the laboratory transmitted 12 h.p. when first put on the pulley at a slip of 1.2 per cent. After five hours running it reached 19 h.p. with the same percentage of slip and the same tension. At the end of 13 hours it transmitted 24 h.p., and reached 31 h.p. after 20 hours with a slip of 1.6 per cent. According to horsepower tables, its scheduled transmission should have been 26 h. p.

Summary of Results

Inasmuch as the belts in these tests seemed to be typical, and the apparatus at hand was such as to give the most accurate readings of performance, it is safe to conclude that the results are scientifically acceptable. To review the details of each individual test would require more space than is here available. Suffice it to say that a summary of all of the results is clearly in favor of the grain side from the standpoint of power transmission. In fact, it may be concluded from it that under reasonable shop tension, the flesh side will average only 50 to 60 per cent. as much horsepower as the grain side. At higher tensions the flesh side will do better, averaging from 50 to 100 per cent. as much power as the grain, depending upon the belt, the tension and the conditions of service.

A curve plotted from the readings taken when the belts were running on the flesh side is similar both in shape and capacity to that given by many of the leather belt substitutes. All that can be said of the test belts run on the flesh side is that the data obtained from them were more uniform than that taken when they were running on the grain.

Using the horsepower transmitted and the percentage of slippage as the coordinates, on chart at Fig. 1, which is representative, the grain tests showed an almost curveless gain in horsepower up to 53, when the slip reached about 3 per cent for belts running at a slow running tension of 432 pounds. In the case of the test belts operated at a slow running tension of 288 pounds, the 3 per cent. slippage was reached at about 44 h.p. With the belts running on the flesh side, however, the 3 per cent. slippage mark was reached at 28 h.p. when operated at a slow running tension of 432 pounds, and at 16 h.p. when the tension was 288 pounds.

In short, the evidence produced from the mass of data obtained leaves no reasonable doubt but that there are distinct advantages in power transmission to be had from running leather belts on the grain side. It is simply another case where scientifically obtained evidence must outweigh arbitrary opinions held usually by reason of personal and, oftentimes, inaccurate observation. It would seem to indicate that all those who have held the flesh side in favor in years past would do well to readjust their opinons, and if there be any alive today who are still determined to bring Providence into the discussion, they must find some providential reason for putting the flesh side of leather next to the animal and the grain side next to the pulley.

TREATMENT OF OIL

(Continued from page 44)

and treating apparatus receives in service. On this account, mechanical shops, having carpenter, machine, boiler, blacksmith and pipe departments are a regular installation.

The customary equipment for the carpenter shop is a bandsaw and planer, and for pattern work a wood lathe is useful. The machine shop equipment preferably consists of two lathes, a planer, two drills, a tool grinder and bolt cutter, as well as the miscellaneous small tools, incidental to a well equipped machine shop, plate rolls to handle plates up to 16 feet wide are used, although some situations can be cared for by 12 ft. rolls. In addition, a power operated punch with at least a 36 inch throat and fitted with a shearing device is a necessity, as well as a full complement of air drills, hammers, etc. The blacksmith shop should have a steam hammer, as well as the usual hand forges, etc. The pipe shop should be equipped with two pipe machines, one to cut and thread pipe from ½ inch to 4 inch and one to handle up to 16 inch O. D. pipe, and in addition, the usual complement of hand tools for cutting and threading up to 4 inch pipe should be available for use outside the shop.

Tank cars require regular repairs, and these together with the repairs incident to refining necessitate a storehouse of ample capacity, fully stocked with standard hardware and equipment specialities, as well as brick, lime, cement, etc.

It is rather difficult in an article of this kind to cover matters in as great detail as perhaps the importance of the subject justifies and in case anyone is further interested in petroleum refining and wishes to read an authentic publication, no better selection can be made at the present time than Bacon and Hamor's American Petroleum Industry.

DRILLING AND BORING MACHINE

The Manufacturers' Consulting Engineers of Syracuse, N. Y. have designed a machine that simultaneously drills three holes and bores a fourth in each end of an automobile crank case at one time. This machine, in one operation, does the work formerly accomplished in three, and the bed is supported on floor legs and carries its own electric motor. Two sliding heads are provided, each carrying three drills and a boring head. The number of drills and the tooling can be altered to suit the job in hand. The heads are located at opposite ends of the bed, the work clamped between them. One lever actuates both heads, and by means of this lever the heads are fed towards the work, the arrangement of feeding being somewhat similar to that of a sensitive drill.

RAPID HOLDING AND RELEASING OF GEAR BLANKS

(Continued from page 41)

vices, and a single lever motion operates the set with one movement. Another inception imitates the continuous millers, there being a turret base to hold sa two batches of four blanks, one batch being cut while the other set is swung out and removed, and fresh blanks put on. Thus there need be no interruption to the cutting.

Economy, Conservatism and Efficiency Needed

Trend is Towards More Stable and Active Conditions—Improvement Will be Gradual—Mercantile Business in Better Shape—Obstacles in Reducing Costs of Production

By HERBERT P. HOWELL
Vice-President of National Bank of Commerce.

THE PRESENT business situation is distinctly a two-sided proposition. There is much in it to be encouraged about. There is also much to be regarded seriously. Either an optimist or a pessimist can cite plenty of facts to support his case. We have had many exponents of both schools making out plausible cases. One may study the situation and find grounds for declaring that no great financial problems remain to cause anxiety. The other may look at events from his point of view and find justification for his fears that grave difficulties still confront business.

Both are partly right. But I have no hesitation in asserting the conviction that the favorable factors outweigh unfavorable ones. We are not going to have another great and rapid revival of business such as the optimist might feel justified in hoping for. But we can unhesitatingly count on a continued gradual trend of developments toward more stable and more active business conditions.

Business was in far better shape at the end of 1921 than at the beginning. It will be in better shape at the end of 1922 than it is now. In net results 1922 will be a better year than 1921. We might qualify this statement by saying 1922 will be better, provided business men as a whole continue to act sensibly. We might say that developments will be favorable if economy, conservatism and efficiency rule in business, rather than efforts at stimulation and expansion.

Business Not Speculation

But it is not necessary to make that qualification in words. It is inherent in the facts of the situation. Conditions are such that economy, conservatism and efficiency will prevail in business because the pressure of circumstance compels observance of these measures. Business that tries to run ahead of the conservative progress of the times toward normal will be liable to disaster. Efforts to spread out will bring disappointment and failure. Lucky individuals may run ahead of the game for special reasons. But as a rule 1922 will be a good year for remembering above all that business is business and not speculation. During the boom, business had to speculate despite itself due to the rapid change of circumstances. Rising markets often made it unsafe not to go long without materials. Failure to expand under conditions then existing seemed like turning one's back on opportunity. But that is not true for 1922. Undue stimulation and expansion simply will not work this year. The market will not take them.

Profits can be made and success can be established during 1922. But they must be built up by means of economy and efficiency within the bounds of conservative business operations. A lower turnover is inevitable. There is a rigid price resistance from the ultimate consumer that must be accepted. Therefore, profit margins in business must be effected by economies in production costs. There are definite reasons for the statement that the improvement in business during 1922 will be gradual. Enough favorable aspects are obvious in business to encourage confidence, but not to warrant any relaxation in vigilance and care.

Banking Situation

Foremost among favorable factors in the general situation is the condition of banking. Fear need not be felt regarding the ability of worthy businesses to command adequate banking facilities and at reasonable rates. The banking situation is strong because the underlying conditions upon which the structure rests have been strengthened. At the opening of the year 1921 bank credit was characterized by inflation, nonliquidity and widespread insecurity. During the course of the year there has been a material reduction of nonliquid and unsound credits.

There has also been considerable reduction in the total volume of credit in keeping with the progress of liquidation, falling prices and reduced business activity. There is more gold than the country needs as a basis for its credit structure, and there must be no disposition to inflate credit on the basis of this gold. The high reserve ratios caused by the presence of this huge gold supply must not lead us into easy credit and unsound money policies. The very bulk of our gold reserves emphasizes the warning that the operations of sound business, not the ratio of gold reserves, must remain the basis consideration in credit extensions. The more healthy conditions in the investment money market make it possible for commercial banking to adhere to strictly commercial business. Investment funds are available for long time requirements. The banks are free to take care of current needs as is their function. Thus in all major aspects the nation's banking system is in an unusually strong condition.

Inventory Valuations

We can also feel that mercantile business is in far better shape at the end of the year than at the opening of 1921. There has been a widespread adjustment of inventory valuations. During the boom many ill-conceived businesses sprang up and flourished due to easy conditions for success. A horde of speculative middlemen came into being. The more rigid competitive conditions of the period of reaction have eliminated many of these various classes of business units. It has not been a pleasant process and while not complete, it has created a stronger mercantile business situation. It has also resulted in the removal of many obstacles to the establishment of fairer prices for the consumer.

In industrial business also, conditions are sounder at the end of the year than at the beginning. The general inventory position has been improved. There has been a return to a greater degree of corporate economy. There has been, as a result of unemployment and competition for work, a development of greater man power efficiency. Wage reductions have contributed to the bringing down of production costs.

Price Situation

The price situation is also better. The period of avalanche price declines is over. This movement was still in progress at the opening of 1921. After a period of business activity for nearly twenty years with rising prices it was a new experience for business to have prices start downgrade. The present generation scarcely knew how to do business under such circumstances. Although many prices will continue to recede, business and banking are now better schooled to cope with that situation. We need hardly fear a general price demoralization.

The attitude of the public in respect to buying is now a more calculable business factor. In the first place any thought that the public will buy at almost any price can be eliminated from business calculations. It can be set down as definite that the public has become thrifty and discriminating in buying. Decreased purchasing power and unemployment have made it so. People are willing to buy what they require so far as they are able and where they can find fair prices. A thrifty public, in the long run, is better for business than is an extravagant public.

With all these facts of betterment, why should the decision not be rendered in favor of the optimist? Because on the other side of the picture there are certain serious elements of maladjustment that cannot be ignored. There are impediments to the healthy functioning of the markets and difficulties in the way of a complete readjustment of the costs of production and distribution. These obstacles must be overcome before anything like a fundamentally normal business situation can be re-established.

Cost of Production

Among the obstacles to reducing the

costs of production and distribution are certain classes of wages. Mining, transportation and building labor must be further readjusted. The effects of these still relatively high wages permeate all kinds of business. There can be no thoroughgoing completion of general readjustment until these sources of high production and distribution costs have been dealt with.

Similarly, on the cost side of doing business, is the burden of taxation. The country's obligations must be met by taxes. Relief in this situation must be worked out through the difficult process of reducing current government expenditures and through shifting the burden of necessary taxation so as to reduce as much as possible its hampering effects upon productive enterprises. The new tax law and reduced aggregate tax levy are encouraging features.

Again on the cost side of business are the debts created by the extensive funding of current obligations following the boom. This has created interest and amortization charges against present and future earnings. Also, the burden of high overhead charges from extensive, over-built or idle plant equipment has to be reckoned with.

These various sources of special production and distributing costs add to the difficulties of doing business, of reducing prices and, therefore, to the slowness of recovery. While they are operative they must be met by economies in other directions. It can be said that never before in modern industrial history has there been such a pressing need for economy, never before such an imperative necessity to reduce wastes and increase efficiency.

On the cost side of business must be cited the high-priced inventories still to be reduced. Despite the general progress made in inventory readjustment, there are many lines yet carrying a heavy burden here. Impaired buying power made impossible in many cases the distribution of stocks at prices covering production costs. It seems inevitable that some further losses must be taken on this account. Here again there appears to be no alternative but to offset these losses by unusual economies in the total activities involved in handling such stocks.

On the marketing side of business we are confronted with a choppy condition of prices. Many prices have gone much further toward the prewar basis than others. This has made impossible, for instance, the absorption by the agricultural communities of normal volumes of retail goods whose prices have not fallen to so great an extent as have prices for farm products.

Further Changes Expected

Again, as to market conditions, although some prices have apparently reached comparatively stable levels and no general collapse is to be feared, nevertheless there are some prices where further changes are to be expected. This is true where excess stocks of raw products are overhanging the market because of over-production or impeded distribution. Further downward movements may be expected here. On the other hand, there are undoubtedly some prices which will be driven temporarily upward in cases where there has been too great a curtailment of production. As existing stocks are absorbed shortages may develop. In general, the price situation is characterized by a number of inconsistencies.

There is the effect of the situation in the world markets upon domestic industry and commerce. America is a quantity-production country. It must therefore have world markets. This is broadly true in respect to agricultural products. It is also true in respect to many of our manufacturing industries. The consumption demands of America alone are not sufficient to absorb the total outputs of such productive interests at prices to keep them fully employed on a satisfactory basis. Excess production must be sold in the markets of the world. While the world markets are in their present demoralized condition, the marketing of such surpluses will be a problem.

We have the resources and are equipped to do a tremendous business, both in the domestic field and in the foreign field. But the markets, both in the domestic field and the foreign field, are still greatly out of gear. Business cannot go ahead with the full swing of confidence and prosperity until these are brought back into gear. In the foregoing I have attempted to picture the structural framework of the present business situation. It is obvious that further drastic readjustments must be made. These readjustments, looked at in detail and detached from broad considerations, may seem in some instances to imply adverse effects upon one class in the community as distinguished from others. This is a narrow view to take of them. It is perhaps the natural human view. The human element in business is a factor to be considered as well as the foregoing more technical aspects.

Standard of Living

For instance, in the case of wage readjustments, there is nothing in that suggestion inimical to the interests of labor. Arbitrary money wage scales are obviously not the fundamental consideration in the best interests of the worker. Business activity, steady employment and maximum purchasing power of wages are really what give labor the standard of living it demands. In so far as reduced wages help restore business activity, bring about steady employment and reduce the cost of living, the interests of labor, business and the general public are absolutely identical. It is a hopeful sign of the times that most classes of labor have accepted this viewpoint.

Again, the requisite further reduction of retail prices may seem to imply a readjustment bearing more heavily upon one business element than another. But the case is not different in essentials from that of labor. What the retail business men obviously want are volume and steadiness in business. It is, generally speaking, immaterial to them what price levels prevail so long as there is a fair margin between selling and buying prices. As general living costs go down a narrower net profit gives as much purchasing power as would a greater profit when general living costs were up.

Lower retail prices will benefit the public and benefit the merchant by stimulating his sales. It is an impulse for better business activity that will flow back to the ultimate sources of production. It will help in the clearing up of difficulties of all stages. These instances of wages and price readjustments are cited to emphasize the community of interest that all elements have. The cases named are not different from others that might be mentioned.

What Deflation Means

It is not the carrying out of these movements that causes injustice. No business element can expect to see corrections in other phases of business and avoid a similar process in respect to its own. No class in the community can expect to enjoy the benefits of deflation without sharing the burdens. Deflation, if it means anything, means a reduction of incomes as well as expenditures. It means a reduction of consumers' as well as producers' prices. It means a reduction of wages and salaries as well as profits and dividends. But it need not mean a reduction in general standards of living if these various reductions proceed to a state of equilibrium.

There can be no equilibrium if any element in the community by resisting readjustment seeks to establish higher real wages or higher purchasing power for the fruits of its efforts than are justified by economic relationships with other phases of industry, commerce and finance. Fortunately we can rely upon economic forces to go forward impartially. They are no respecters of persons. In the long run they will not permit any class, to intrench itself permanently, as a result of war and postwar conditions, in a more favored position than the intrinsic value of its services to the community as a whole warrants. The market will determine these values. The year that lies ahead, I am confident, will see a progressive smoothing out of the inequitable conditions now prevalent in business.

There perhaps has been a suggestion of business fatalism in what has been said. The outlook for the year, it may have seemingly been implied, is that business men will be subject to economic forces beyond their control. It has been said that economy, conservatism and efficiency will prevail because there is no alternative. It has also been said that economic forces will control the course of events.

Effective Ways Being Found

I am no fatalist. In the past, with recurrent eras of prosperity and depres-

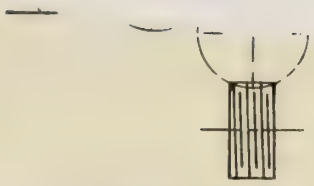
Fig.

A radius bar . . .
tres of the pivoting holes being drilled to the exact distance of 15¾ inches, this being the radius of spherical surface desired. After disengaging the nut and screw in the cross slide, one end of this bar was pivoted to the bracket, securely clamped to the tail stock spindle, and the other end located on a shouldered stud and screwed into the top slide of the tool rest.

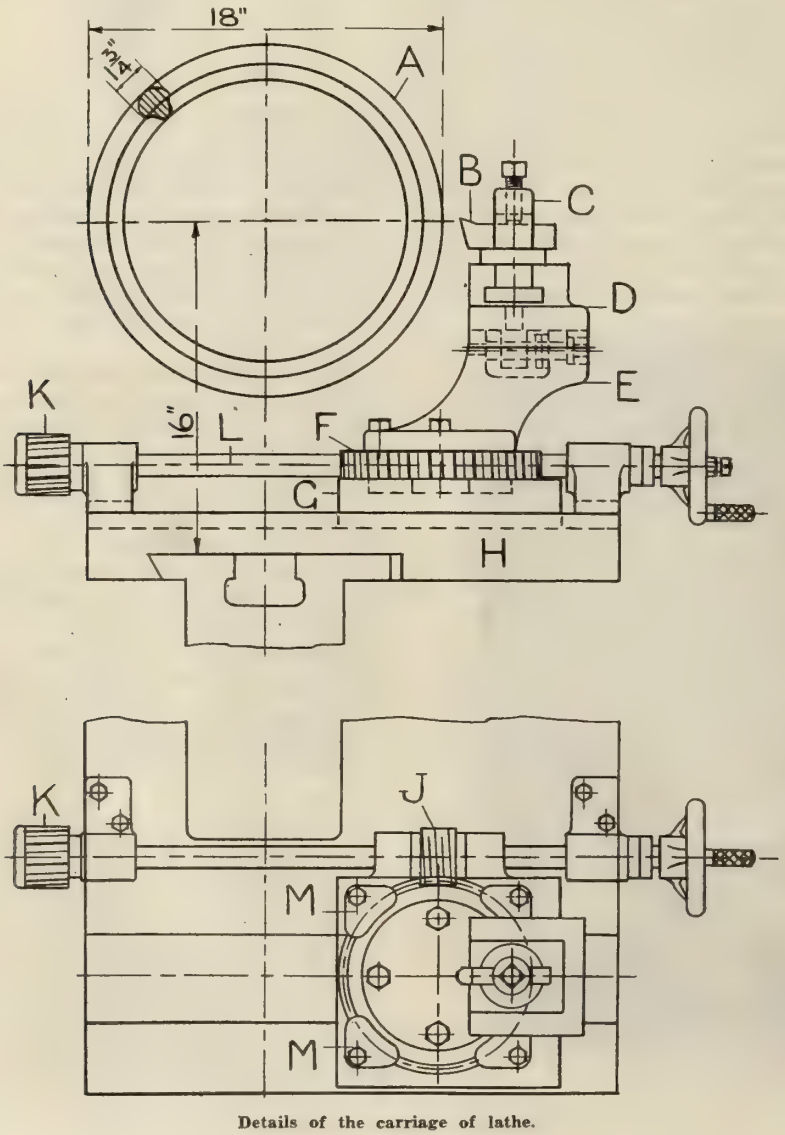


It was of course necessary to ensure that the tool point was located on a line parallel with the lathe ways, and running through the centre of the pivotal stud in the tool rest. Setting the tool point on the centre line of the job, the tailstock barrel was wound out until the radius bar registered parallel with the ways of the cross slide.

It only remains then to wind in the cut and traverse the saddle backwards, an appr. . .
duced in the or. . .
large variation in the rim
while in the handwheel turning lathe to be described they were turned out quite uniform and at a greatly increased rate.

It should be stated that the maximum diameter of handwheel used is 18 inches and the minimum 6 inches. The lathe is built from standard 16 in. swing lathe patterns. The bed is straight, 7 ft. long and carried on two shallow cabinet legs. The standard driving headstock and tailstock are utilized but these are mounted on raising blocks on the bed which gives a distance of 16 ins. from the lathe centres to the bed top or a swing of 32 ins. over the bed. The driving headstock is fitted with a three speed driving cone and duplex back gears which in combination with a two speed countershaft gives 18 turning speeds. In designing the lathe. it was arranged to use same for turning up pulleys if the output of handwheels was satisfactory. For this purpose a special 4 tool turning rest is provided and the usual hand and automatic sliding and surfacing traverses but no screw-cutting motion.

Showing method of producing special surface.



End view of tool post

The principal feature of the lathe is of course, the tool rest and carriage and three views of these are shown in the accompanying line drawings. "A" is the handwheel to be machined and the cross-section of the rim shows that the portion to be turned is rather more than a semi-circle. "B" is the cutting tool mounted in a round steel toolholder "C" and secured by a set screw. The top slide "D" has a slight adjustment on the main rest "E" in order that the tool may be readily set in position. It will be seen that this rest is shaped away to clear the largest handwheels, and it is secured at the base by set screws to a worm wheel "F," having 60 teeth, ½ in. pitch.

This worm wheel is recessed into a square slide "G" which has the usual adjustment across the carriage "H" by a surfacing screw. The worm wheel is operated by a 4 ins. diameter right hand double thread worm "J" which receives its motion from the usual train of lathe feed shaft gears, pinion "K" and worm shaft "L." The worm shaft is hollow and a friction rod passes right through the same to the front enabling

...rim ... this lathe has been worked by both girl and boy labor, and the output with regard to both quality

Details of the carriage of lathe.

...ve up
...rnative was a better scheme anyway; a piece of 1-16in. sheet iron was cut the size of the face of the shell, concaved through the centre to a slightly smaller radius than the journal, and secured to the shell by "C" clamps. Then the shell was turned on end. Pouring such a bearing on end always leaves a denser, cleaner lining of the kind that shows up free from lines and holes when bored.

No ladles were available larger than the small hand type that hold about 50 cub. in. of metal, and we had to provide eight times that amount. An ordinary household iron kettle of the kind whose diameter about equals its depth, and having, besides a good bail, a ring on one side for tipping, took the place of a ladle.

The metal was heated in the forge, near which was placed the shell standing on the concrete floor and having a good riser built up on top. A more perfect job than this equipment turned out would be hard to find. Before the babbitt had entirely cooled, workmen started to peen it, going over the entire surface and hammering the metal to a greater density and making it tighter than ever in its grip on the undercuts.

Boring Operation

Boring was the most particular of the jobs involved. We had a lathe with flaring wings on the carriage. These were "T" slotted, and we had "T" slotted paral'els that we bolted to these wings to form a work table for various boring jobs. A 3in. boring bar was available, though we had to make a special tool to reach the large diameter.

It was decided that a better job would result if the three other parts of the bearing were skimmed out at the same time, removing just enough material to clean the surface. In setting up, the bottom shell was first lined up with the bar and placed at the correct height and clamped. Then angle plates were bolted to the parallels at each side of the bottom shell, forming a skeleton opening similar to that in the engine

(Continued on page 52)

Horizontal Drilling, Milling, Facing Machine

By H. A. WILSON

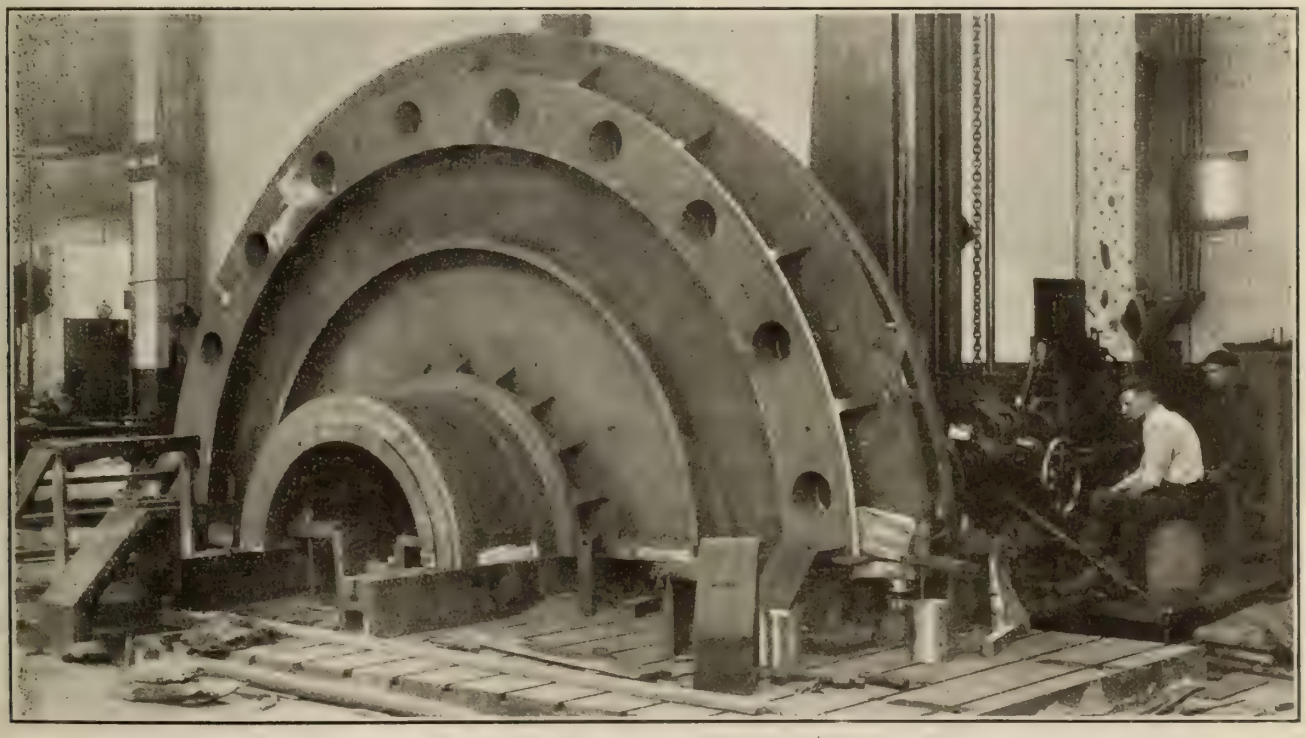
IN DISCUSSING portable and stationary tools, at first consideration, one is liable to imagine there is a distinct line drawn between the two classifications. However, in the machine described in this article, we find a stationary tool that has many of the advantages of the portable type.

By referring to the illustration, it will be seen that the tool is used to machine very large pieces. The casting shown is one half of a head cover for a 11,300 h.p. turbine for the Cedar Rapids power development. The complete turbine is being built at the Dominion Engineering works, Lachine, P. Q. and the casting was produced in their foundry.

The remarkable part of the story of ths machine is that it is not a product of any one machine tool builder. It was devised, partly manufactured, and assembled in the Lachine plant, and a great variety of work is being constantly taken care of by this machine. Practically all work is of a heavy nature which will perhaps better explain some of the reasons for several unusual features in the design.

Details of Design

The bed of the machine consists of two old lathe beds which have been bolted together. These beds are not of the modern design having "V" ways, but have the old fashioned, flat type of way. The combined length of the two lathe beds, makes a bed for the machine which is nearly fifty feet long. There are two columns mounted on these ways, each carrying a horizontal gun-boring arbor mounted on a head complete with all feeds actuated by power. The columns were designed and built at the plant.



The bases of the columns are machined to fit the lathe bed ways, in such a manner that they permit the columns to slide along these ways. Of course, the bases of the columns are rather wider and longer than the cross section of the columns to permit of a large bearing surface on the bed. The columns can be locked to the bed in any desired position, and at the base of each column on a machined flanged projection is located the head of a Jones and Lamson flat turret lathe. The constant speed driving pulleys of these heads are connected by belts to electric motors each mounted on a bracket on its respective column some five feet above the heads.

Instead of a face plate, or chuck, on the live spindle there is located a cut tooth sprocket wheel. This sprocket wheel drives by chain a second sprocket wheel on a brass nut which is located on a feed screw extending from end to end of the bed. Thrust washers are placed each side of the brass nut, (separating it from the two column lugs, one on each side of the nut,) which, when operated by the turret head lathe moves the column along the ways. The clamping studs are always slacked off before moving the column. The full range of speeds, originally intended to be spindle speeds, are available for feeding the column along the ways.

Feeding the Boring Bar

A second motor is located on the top of the column for driving and feeding the boring bar and moving the head up and down the column. Electricity is supplied to these two motors from live wires located below the top of the bed, (and therefore, below the floor level) and a set of sliding contacts for each column. The columns have vertical ways machined to fit the heads carrying the boring bars. The heads are counterweighted, the counterweights being hung inside the hollow columns.

A switchboard controlling the top motor is located on one side of the head within easy access of the operator standing in his normal position. An operator's platform is attached to the boring head and when the head is raised up the column, the platform wth the operator is also carried up. Gear boxes giving a full range of speeds and feeds are incorporated in the design of the

This view shows clearly the capacity of the machine.

head, and this, together with the electric control board, gives a very concentrated control system. One man can operate all the control but owing to the size of the machine and the large castings machined, it takes two to handle the work, as one man must be practically constantly observing the action of the tool, not only when locating and placing same in the work, but as it continues cutting.

Then too, when the column is being fed along the ways longitudinally, the control of this feed being largely in the turret lathe head, one man must be available to operate them. A large machined floor plate cast in sections, having numerous parallel "T" slots cut in it, extends along the whole length of the ways. On this floor plate all work is set up, and in these set ups a large number of parallel bars, angle pieces, "V" blocks, etc., are used.

Among the commoner operations performed are the following:—drilling, tapping, reaming, milling, facing and boring. In the drilling operation the column is always locked on the ways and the proper speed and feed selected for the diameter of drill to be used and the material which is being drilled. Of course, in locating the drill the column is moved along the ways and the head travelled to the proper elevation on the column. A hand wheel is provided to rapidly bring the drill up to the work before throwing in the automatic feed. In reaming much the same procedure is followed. In tapping operations special fixtures are necessitated in order that the tap may take its proper lead after it has been once entered.

The milling operations with a face mill, or a side and face mill are usually confined to milling keyways in large turbine shafts and similar work. The facing of various surfaces is done largely with large diameter cutters having inserted blades. End mills are used to cut keyways in certain shafts. On the whole the application of a milling cutter to this machine enables a wide variety of jobs to be undertaken. Boring operations can also be accomplished in a multitude of ways.

Usually the large castings are placed on the floor plate after being marked and laid off. They are then clamped in position and remain in the one position until all operations possible are completed. Thus, some of the fundamental ideas of a portable tool, (that of bringing the tool to the work,) are embodied in this machine; which is really classified as a stationary tool.

The power of the motors installed is more than ample to drive large diameter drills, and large inserted tooth milling cutters, as well as take care of the feeds. The main screw, extending along the whole length of the bed and placed centrally between the ways, does not revolve. There are several interlocking and more or less complex reasons for this feature among which is the dual reason, that as it was primarily decided to use solid feed nuts which were positively connected to the turret lathe heads, it was the only method that could be employed which would enable the two heads to be operated independently of one another, and secondly, it compactly placed all moving parts at the column, where they were directly under the observation and control of the operator and his helper.

The tool is one that is rarely idle, and more often than not, both boring bars are operating. The work passing through this particular shop is so large that it would be very costly to have to reset these castings several times to accomplish work that is accomplished at one setting on this machine. Another reason responsible for a certain volume of work being handled on this too, is that the engineering department design many pieces, and route them via this machine, knowing full well its versatile qualities and its ability to get through many ticklish jobs.

ECONOMY AND EFFICIENCY

(Continued from page 48)

sion, it has sometimes seemed as though business were subject to the coming and going of inexorable tides. In the present situation, too, the war set forces in motion that have seemed overwhelming. But I am confident that effective ways are being found to diminish these conditions.

Never before was there a greater demand for individual initiative in business, never before a greater need for penetrating judgment. Recognition of the larger principles controlling business conditions does not mean an admission of helplessness. These principles are guide-posts to success, not barriers to individual achievement. To say that the times require to an unusually high degree the practice of conservatism, economy and efficiency is only to say that they require the intensive application of the methods by which, in the long run, the lasting and substantial progress of the world has been built. The full fruits of brilliant pioneering enterprise, in whatever field of endeavor, would never have been harvested had not discovery been followed by hard work.

There has developed at the end of the year just closed a remarkably general consensus among those qualified to pass judgment on business conditions that the worst is over and better times lie ahead. In this judgment I heartily concur. The year 1922 may not be one of great realizations and fulfilments, but it will be one of laying the strong foundations for better businesss in years to come.

AUTOMATIC ARC WELDING

Just as the increased use of resistance welding quickly brought into use automatic devices for increasing speed and reliability of product, so the automatic electric arc welding machine promises to find an important place in this form of welding. This type of machine will weld at a rate of from two to six times the rate possible by skilled operators welding by hand, due to the stability of welding conditions and the elimination of the necessity for changing electrodes. The characteristics of practically all electric arc weld machines premise that current and voltage are interrelated, an increase in one causing a corresponding decrease in the other. The automatic arc welding machine utilises the arc voltage as a basis for regulating the equipment. A shunt-wound motor having the armature connected across the welding arc will vary in speed as the arc lengthens or shortens, due to the variation of the arc voltage. "Now," continues W. E. Rudder, in the journal of the Franklin Institute, "if this motor is connected through suitable gearing to the electrode wire, the wire will be fed into the arc at a rate depending upon the arc voltage it is desired to maintain.

"A vibratory relay is also connected across the circuit in such a way that the relay contacts open when the voltage increases. This cuts resistance into the field circuit of the feed motor, still further tending to increase the feeding speed. As a result, the wire is continuously fed into the arc at an almost constant rate, and the electrical conditions, as indicated on the switchboard instruments, are very steady. As is the case with other automatic machines, the principal field for the automatic arc welder is one where a considerable amount of welding is required calling for a continuous repetition of duplicate welds, building up pulleys, shafts or worn bearings."

ELECTRICAL ACCIDENTS IN FACTORIES

A practical point in factory administration is the procedure to be adopted in cases of electric shock.

The rules are generally to be found exhibited in most factories, but there seems to be much ignorance as to what to do when a person is rendered unconscious by an electric shock, and the charge is made not only against employes and employers, but also against ambulance men, and even doctors. The importance of commencing artificial respiration at once, and keeping it up for at least two hours, cannot be overemphasized.

RENEWING BEARING

(Continued from Page 50)

frame. The quarter blocks having been shimmed and bolted, the cap was clamped on and boring commenced.

Little remains to be told. Chipping the oil grooves was the most tedious job of all. A splendid fit and equal alignment were obtained. Three days after the parts were laid down on our floor, the work was finished. Probably the factory wouldn't have bettered this much. The babbitt used was purchased from the street railway, of a grade put out for motor bearings, and seemed well adapted for this other work.

sell wire and nails to customers in Cleveland at 10 cents per 100 lb. over the Pittsburgh basis, when the material is made in Cleveland, instead of at the Pittsburgh price plus the rail freight Pittsburgh to Cleveland. While in various products there have been divergences from the "Pittsburgh plus" system of quoting delivered prices, even by the Steel Corporation, it is a new thing for the corporation to do this openly in wire products.

Mill Operations

The official report on steel ingot production in January is awaited with unusual interest, as mill operations have been so irregular that it is difficult to make a very close estimate as to just what they have been doing. Last July steel ingot production was at the rate of 11,000,000 tons a year, the rate increasing until in October and November it averaged 23,000,000 tons. During December production declined, averaging about 20,000,000 tons a year during the month, but being at probably no more than 18,000,000 tons towards the close of the month. The rate in January probably averaged around 18,000,000 or 20,000,000 tons, whereas a quick return after January 1, to the 23,000,000 ton rate was expected, with further improvement as spring approached.

Pig Iron and Coke

A Pittsburgh district steel interest inquired for 1,000 tons of basic iron and drew quotations from valley furnaces at $18, furnace, against the former nominal market of $18.25. The purchase, however, was made on the basis of $17.75, valley, a middle interest offering some resale iron at this figure. The identity of the iron is not known positively, but rumor has it that it is part of a large block of iron which a steel mill has due it and cannot use, the contract price of the iron being more than $10 a ton above the price now realized. The basic iron market becomes quotable at $18, valley.

Foundry iron is down 50 cents to $19, valley, on purchases of two lots of 500 tons each from valley producers by the Standard Sanitary Manufacturing Company, which has been running full for months, except for a short closing at holiday time. Bessemer is unchanged at $19.50, valley.

Connellsville coke continues in very poor demand, spot furnace coke being available at $2.75, or less than the cost of production. Foundry remains at $3.75 to $4.25 depending on brand.

The Pittsburgh district coal operators, who have had little business in recent months on account of the high wage scale of the United Mine Workers, running to April 1, as the business has been going to non-union fields such as Connellsville, have announced the wages they are prepared to pay beginning April 1. The scale is about 32 per cent. under the existing rate. Allowing for the difference in ease of mining it is in proportion to the rates now being paid in the Connellsville region, and the trade assumes that this means there will be no further reduction in wages in the Connellsville region.

POINTS IN WEEK'S MARKETING NOTES

Montreal says sheets have improved slightly but that merchant bars are still dull. Prices are weak, these being sometimes close to actual production cost.

The machine tool market is dull. Small tools and supplies are selling much better, non-ferrous metals are inactive, and scrap metal is also very quiet. No immediate improvement is looked for in the above lines mentioned as dull, although small tools look much stronger as the year proceeds.

The local market is stronger. A certain amount of equipment has been sold to the Durant Motors, but not nearly as much as originally planned. Other machine tool dealers report a fairly good week.

Steel dealers claim that January has been a fairly good month, but a typical January, which means hard work to bring the order total up to anything like a good figure. Competition is keen, and several reductions in price will be noted in this week's quotation sheets.

The looked for revival in steel products has not materialized, says Pittsburgh. Tin plate shows up best of all, the mills running at about 75 per cent. capacity. Some are looking for a new record in tin plate production this year.

Tubular goods are falling off in demand, oil country goods having eased off considerably. Bar demand is very spotty, and price shading is occurring in practically all lines, especially where the order is of decent proportions.

Plain wire and wire nails are selling at varied prices; 2.25 cents for the former, and $2.50 for the latter is about the average. One concern is selling in Cleveland at 10 cents per hundred pounds over the Pittsburg basis, when the material is made in Cleveland. This is a new practice to openly quote in this way.

Basic pig iron is quoted at $18.00 from valley furnaces, although a recent purchase was made at $17.75, this being on re-sale iron. Coke is in poor demand. Coal operators have announced their new wage scale which is about 32 per cent. under the existing rate.

Through the introduction of one-man street cars by the Saskatoon Street Railway, a decrease of $50,000 in the company's deficit for 1921 is shown in the annual report.

SMALL TOOLS STILL IN GOOD DEMAND

TORONTO, FEB. 1st.—The local market is rather spotty because while some dealers are securing satisfactory business, others are doing practically nothing. It would at first appear as if the dealers closing few orders must be resting on their oars, but this is not the case. Generally speaking, everyone is on their toes, exerting every possible effort to secure business.

Competition is keen, prices are being shaded, in fact in some cases are cut to the bone, with the result that the small fellow who cannot afford to drop to such a low level is left behind. This is not always the reason, but in many cases, price cutting is the deciding factor.

Steel Market

Activity on the steel market remains much about the same. No special line is featured. Iron and steel bars are listed on this week's quotation sheet at 2.90 but this price is often shaded to 2.75 when the order is tempting enough. However, as 2.90 seems to be the average, we placed it that way on the quotation sheet. Hoops are selling at 3.75, blue annealed sheets No. 10 gauge at 3.75, black sheets 28 gauge at 4.50, and galvanized sheets 28 gauge at 5.85. Cold rolled steel is quoted at 4.50 base, all the above prices being fair averages. As already stated, a large order usually brings further concessions.

To attempt to feature any one line is impossible in the present market. The demand is general and scattered. Dealers have to work much harder these days to bring the month's total sales up to snuff, because as a rule, orders received are for small quantities, therefore it takes more orders to bring the total up. About the best that can be said for the month just passed, is that it has been a typical January, with a few bright spots here and there.

Machine Tools

The machine tool business continues to be spotty. For example, last week a certain dealer told us business was very poor, but he had several good enquiries out which looked as if they were going to break. This week he tells us three of his prospects gave him orders, with the result he is quite elated, as they were all fairly good orders. In fact three different lines of machinery were purchased.

Not far from this dealer, we visited another who felt things had gone to the dogs. "This has been a very poor month," he said, etc., etc., Next week this same man may have landed some good orders, and tell us that the corner has been turned.

Buyers are walking warily and any purchases they make are considered very carefully. Take for example the Durant Motor Co. This concern had a very large list of machinery planned, yet cut their plans drastically some time ago. The first batch of this new list was

sold by a local dealer a few days ago in the face of keen competition. Further machinery will be purchased, but not at present, according to our informant.

Another machine tool dealer says that although January has not been an exceptionally good month he cannot complain, as he feels he is getting his fair share of what is going. Thus, we have a varied condition, which in many ways depends upon close following up of prospects, plus the right kind of price, viz., a low one.

Metal Market

Iron and steel scrap is fairly active, but only in a restricted way. Mills and foundries are picking up somewhat, this in turn creating a demand for scrap. Of course, the call is light. Hamilton is taking heavy melting steel, its price being somewhat lower, and foundries are beginning to show some interest in scrap, although prices have to be low to make them close.

Copper scrap is being sold at 10.50 to 11.00 cents, and brass mills seem to be running at a better rate. Yellow brass scrap is not in much demand, and white metals are still moving very slowly. The average order is of the hand to mouth variety, so that, although some improvement is noted, conditions have to improve quite a bit yet before dealers will be satisfied.

Small Tools

The small tool and supply market is holding its own. Orders and inquiries are still coming in, and viewed as a complete month, January is a decided improvement over December 1921. Dealers expect still better business in February, and feel that manufacturers are getting more confidence in existing prices. The market in its entirety is stronger and more stable than last week, and from present outlook, should continue to go upward.

SMALL TOOLS AND SUPPLIES THE ONLY LINE SHOWING ANY ACTIVITY

MONTREAL, Feb. 1.—General conditions have not shown much improvement locally in the last week. The movement of steel has not yet increased to any great extent. Sheets have shown a little improvement, while merchant bars are not exhibiting any signs of increased activity. The season of the year is not one where any great improvement in structural steel conditions can be looked for. Business in this line has been fairly active throughout the fall months, and there is a really large programme of building planned for the spring. Plates are fairly active but are not moving quite as satisfactorily as sheets.

Prices throughout are rather weak, and are at present down to a point very nearly as low as the points reached in periods of depression existing in the years just previous to the war. This in spite of the higher manufacturing costs that exist to-day. Interviewing some of the men connected with the bigger interests, there seems to exist a faith in the future that is very strong. At the same time they feel that the present depression is peculiar in the fact that its causes and effects are so interlocked that time is one of the principal elements which must enter into the measures that will prove effective in removing the undesirable conditions. Therefore these interests are awaiting the change for the better with a great deal of patience. It must be fully appreciated that this patience is not of an indifferent nature but one of keen interest.

Artificial standards and conditions set up during the last few years cannot be legislated out of existence. Liquidation has been a great evil, and although it has been considered that the iron working industries had passed through this trying period, for some time back, there appears, from unexpected sources, results of this evil at very trying and irritating times.

No Change

In the pig iron field matters have not changed a great deal. The present low scale of prices is not bringing forth any more business than would have been presented had the prices not been reduced. The fact still remains that the volume of work being done by the machine shops is still small, and the call for castings is very limited indeed. Very few shops locally are working on full time. The producers are quite satisfied not to book any large amount of business at the present prices, as these do not admit of a fair profit and the producer is lucky if he breaks even. Thus, industrial conditions in a general way will have to improve before any great demand for pig iron will be evident.

The machine tool market is still very dull. Dealers do not expect that any great improvement will manifest itself on short notice. Inquiries from varied sources keep coming in, but are not to be taken as any barometer indicating the amount of trade actually moving. Sales of new tools are few and far between. Only a single machine moves and usually it is of a small size.

This Branch Stronger

The small tool business is faring better perhaps, than any other branch of the tool business. These sales, together with supplies, represent practically the whole turnover of the machine tool and supply houses these days. Prices in these lines have been rather steady, but now are gradually going down. This gradual decline is not to be interpreted as weakness, but rather that the competition and the increasing demand, force the manufacturers to give the consumer at least a portion of any reduction in manufacturing costs. The tendency of both material and labor is downward so that from time to time slight reductions are announced.

The non-ferrous metals are very inactive and the prices have weakened in many instances. The business being taken care of by the local houses is all in small lots. No orders of any size have been received for a long time. The present prices are quite as low as the point touched some months ago. At that time it was hoped by all dealers that such low prices would not be seen again. The outlook as far as can be viewed at present is not bright. However, the non-ferrous metal markets are very temperamental and are influenced by factors in all parts of the world. Thus conditions often alter overnight.

Scrap metal conditions are rather quiet. As the markets for metals in semi-manufactured states is weak, it is only natural to see the scrap metal market listless. Quotations are made for each inquiry and these quotations are usually so low that if the scrap is required it will be purchased. The conditions in this market will not likely improve to any great extent until general industrial conditions become better and metals in all their various state of manufacture are in better demand.

GRADUAL RECOVERY LIKELY TO RESULT

Speaking on the economic position in the United Kingdom, Trade Commissioner Harrison Watson says in a recent issue of the Commercial Intelligence Journal, that the new year has opened with a general feeling of uncertainty as to the future, tinged, however, with a considerable amount of optimism.

"Business remains dull and almost featureless," he said, "but it is thought that both trade and industry in the U. K. have touched the lowest level, and that now that the worst is known, gradual recovery is likely to result from the systematic writing down of prices, provision for bad debts, and similar drastic measures which have characterized recent reports and balance sheets of almost every public company in the country. Favourable features are, moreover, the considerable advance in the value of the £1 sterling in America during the past year, amounting to something like 20 per cent, the steady reduction in the prices of commodities amounting to nearly 40 per cent since last January, and the knowledge that the bulk of the Government accumulation of stores has at length been disposed of.

"Upon the other side, there is the knowledge that the financial and economic conditions in a number of European countries are worse than ever, and that the drastic cleansing of the Augean stables which has taken place in this country has still to be faced, which gives rise to the apprehension that the purchasing power of many of the country's best customers must remain seriously restricted for a long time to come."

Geometric
Screw Cutting Tools

Do the Work and Stand Up Through Long and Constant Service

Men long experienced in Screw Thread Cutting affirm they were the losers where they had been induced to try substitutes.

A Geometric Self-Opening Die Head of just the right construction for your work, and a set of Geometric Milled Chasers—Did you ever try to beat that combination on your Screw Machine or Turret Lathe?

A Geometric Collapsing Tap on your Screw Machine, Turret Lathe or live Spindle will prove if it is not the best possible investment.

Geometrics Give Highest Production and Maintain Quality

Right in the Lead

The A. R. Williams Machinery Co., Ltd., Toronto, Vancouver, B.C., St. John, N.B., and Halifax, N.S.

For any thread, any size, any pitch --- there's a Geometric Collapsing Tap or Self-Opening Die Head. Be assured there is one to meet your particular threading need---whatever it may be. Ask us.

Canada's production of asbestos and asbestic in 1920 amounted to 197,321 tons, the deposit of crude and milled fibre being 157,904 tons.

Production for Canadian newsprint mills for 1921 was 90% of that of 1920. The United States mills did not do so well, turning out only 76% of the 1920 record.

Plans have been completed for tunnelling operations on Hamilton, Ontario, mountain face. Work has also been started on the improvements to James St. incline.

London, Ont.—This city's healthy growth may be gleaned from the fact that the population increased from 37,976 in 1901 to 59,100 in 1920, and the value of taxable property in the same time from $25,151,000 to $46,013,550.

The Ford Motor Company of Canada will be in full time production on February 1st. This means that 2,500 employees, who have been working upon a four day-a-week basis since September 1st last year, will go back to the regular six day schedule. The present output of the factory is approximately 160 cars a day and will almost be doubled when the staff returns to full time production.

Preliminary work for the new Port Credit water works system will be rushed through in order that active work may be commenced as soon as the frost is out of the ground. It is hoped to have the plant in operation by next fall. The whole system is estimated to cost $110,000—$60,000 for the central plant, and $50,000 for the distribution system.

The Algoma Steel Plant, Sault Ste Marie, is running around 60 to 65 per cent. capacity, and according to W. C. Franz, vice-president, have orders enough for three months ahead. Mr. Franz believes business will pick up, and that it will come back more quickly in pig iron and steel, because of the need for building and railway construction. In his opinion, low prices have been reached for both iron and steel.

The total export of grain of all kinds from Montreal in the season was 119,602,189 bushels, the significance of which is realized when compared with the previous year's total of 53,143,305 and the previous record of 75,361,829 in 1914. Though wheat showed a substantial increase, the most remarkable development was in corn which from shipments of about half a million bushels in 1920 jumped to more than forty-three million bushels in 1921.

The Manitoba Power Company is building at the Winnipeg river at Great Falls a Hydro Electric plant which will have an ultimate rating of 168,000 H. P. The initial capacity of the plant will be 56,000 H. P. consisting of 28,000 H.P. units. The plant will operate under an effective head of 86 feet. The company is also building 17 miles of high tension lines from the Great Falls Plant to a connection with the existing lines from the Cinawa Hydro Electric Power plant of the Winnipeg Electric Railway Company to Winnipeg.

The Perfect Machine Co., Galt, are making final deliveries this week on the contract for 20 small lathes, 4' x 6" over all, for Toronto Technical School.

Mr. C. F. Rowland, Jr., manager of the Winnipeg plant of the Coco-Cola Co., has announced that work on the construction of a $300,000 plant on Logan Avenue, Weston, Ont., will be started this year.

A committee has been appointed by the Board of Education to undertake the erection of a new Collegiate Institute and vocational school at Guelph, Ontario, at a cost of approximately $300,000. The plans have already been approved by the Department of Education.

The Goldie & McCulloch Co., Galt, have the contract for installing extensions to Guelph waterworks equipment. These include three 9-inch pumps, two of which are auxiliary units, each of three million gallons daily capacity, and one booster pump for fire-fighting purposes.

A design for a viaduct to bridge the Don valley between the suburban districts of Todmorden and Leaside, in Toronto, was submitted to the county council by the county's engineer, Mr. Frank Barber, at a recent meeting. The bridge, with approaches, would be 1 mile and 20 ft. long. The length of the bridge proper would be 1,400 ft., height 130 ft. and width 56 feet. The estimated cost is $870,000.

While admitting that the volume of moving business was, of course, not to be compared with that of 1919, a Canadian manufacturer of machine tools states that he considers it a healthy condition, that his sales efforts are now concentrated on many enquiries that seem to presage a buying tendency. Some of these do not indicate large business, but nevertheless they mean a better tone than that of the uncertainty in the early part of 1921. The demand for woodworking machinery shows considerable improvement.

The Robb Engineering Co., Amherst, N.S., have decided to get their boilers and other type of plate work manufactured in the shop of the Dominion Bridge Company at Lachine, P.Q. The latter company has control of the Robb Engineering Works, and as the demand for boilers which this firm has been receiving is largely from Ontario and points in the vicinity of Montreal it has been decided that for the present, at least, this work could be carried on advantageously in Lachine. It saves the haul of raw materials from this part of the country to Amherst and the shipping back of the completed article. The work at Lachine is done under the direct supervision of the boiler shop superintendent and foremen of the Robb Works. The boiler shop at Amherst is one of the most up-to-date shops of its kind in Eastern Canada. It has in no way been dismantled and the engine works and other lines of activity will be continued as usual in the shops at Amherst.

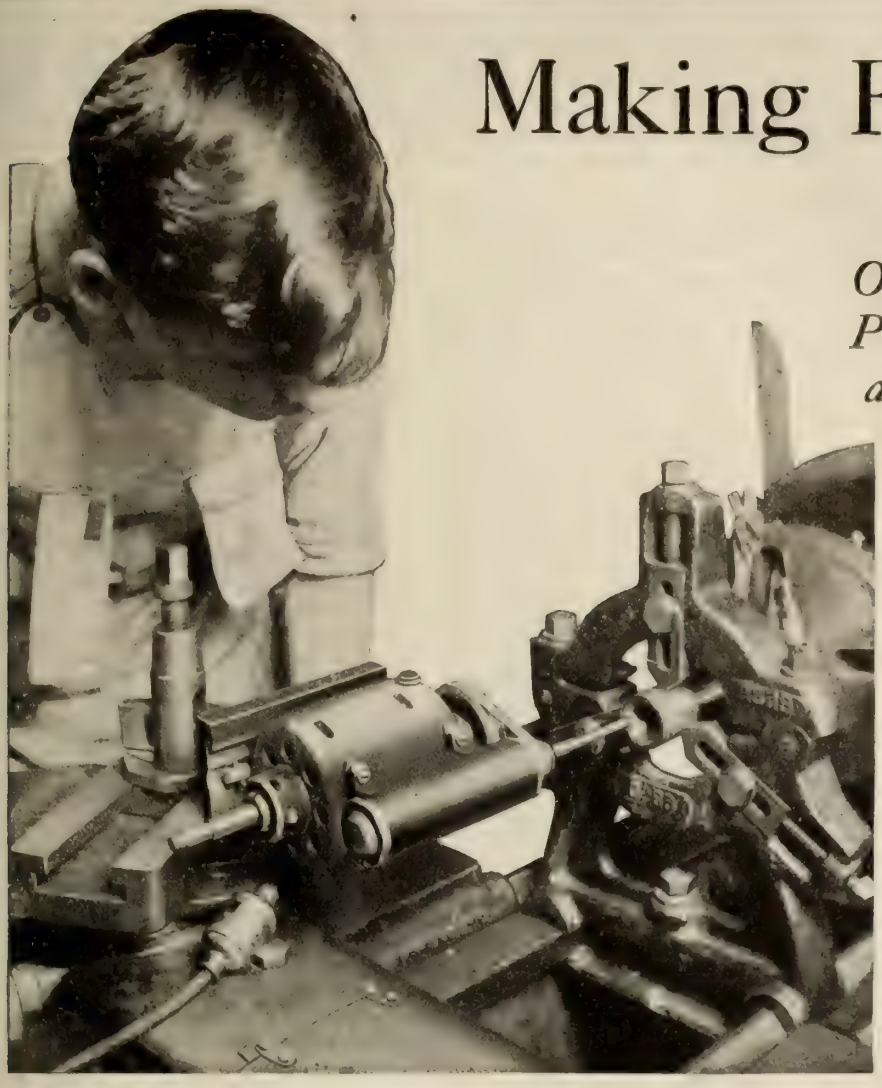
The Railway Roller Bearing Company, Syracuse, N.Y., are re-organizing with the ultimate object of extending the scope of their enterprise.

Contracts for a steel smoke stack for factories costing $25,000 for the Red Arrow Tires Limited, 309 George Street, Peterboro, is awarded to the William Hamilton Co., of the same city.

In 1920 Canada exported to the United Kingdom, United States, Australia, France, Italy, Japan, Spain, and other countries, 152,740 tons of crude asbestos worth $11,521,536.

A report from Ingersoll states that in districts where timber is available there is much activity, a fact which is taken by many to indicate that there will be considerable building during the coming season. The saw-mills in the country are said to be running full capacity.

The draining of a large tract of land for fruit-growing purposes near Agassiz, B.C., is an engineering problem for which the Goldie & McCullough Co., Galt, have supplied considerable pumping equipment. Thirty-inch pumps are being employed at low head for transferring water from low lying land to levels at which it can be easily disposed of.



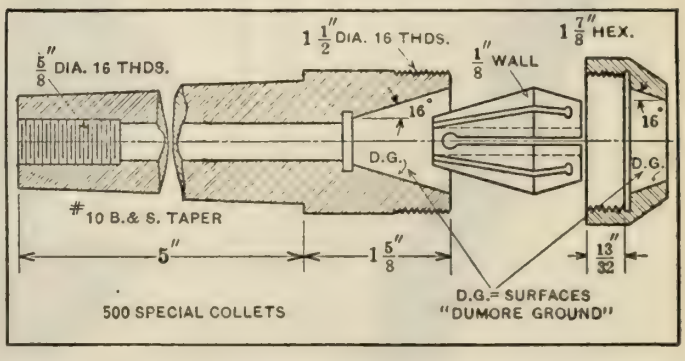
The $6,000,000 plant which the International Paper Co., has had in course of erection at Three Rivers, Quebec, for over a year past, will be started in February, according to a New York report. This plant has a present capacity of 240 tons a day, and the production at the outset will be 100 tons a day. It is the intention to gradually increase the output, and the plant will be ultimately doubled if the market warrants it, with an output of some 60,000 tons a year.

Mr. D. W. Clark has resigned his position as managing director of the Canadian B. K. Morton Co., whose head office is in Montreal, and will in future devote his time to the interests of the Anglo Canadian Wire Rope Co., of which company he is president and general manager. Mr. Clark is well known throughout the Dominion, having covered it for many years from the Atlantic to the Pacific in the interests of the brand of Sheffiield Tool Steels handled by Messrs. B. K. Morton & Co. of that city.

"It is quite feasible to use jackpine in the manufacture of newsprint," said Maurice Neilson of the Belgian Industrial Co., in a paper read before the technical section of the Canadian Pulp and Paper Association at its annual meeting held at Montreal recently. Mr. Neilson stated that his company had been carrying on extensive experiments of jackpine under both the sulphite and ground wood processes, and had met with considerable success. The point was brought out in discussion that available spruce from spruce forests was being rapidly consumed and that the consequence was longer hauls, more expensive wood, and higher priced lumber at the mill. Jackpine on the other hand, was plentiful, cheap, and attained commercial size forty years earlier than spruce.

Making Fine Tools

An Interesting Operation, Economically Performed by Means of a DUMORE Grinder



This photograph — taken at the City Engineering Company's (Dayton, Ohio) plant shows a Dumore Grinder finishing the main shank and head of a special draw-in collet. There were 500 put through in this special lot and the time for the operation shown averaged 8 minutes per piece.

The second operation; grinding the internal face of the collet nut, was also performed by this convenient precision tool.

Dumore Grinders are popular here as in every plant where fine tools are made. Their accuracy makes them useful for the finest finishing work; their simplicity and convenience make them practical for many difficult, almost inaccessible jobs.

Dumore Grinders transform any lathe into a precision grinder; they make fine finishing possible in every machine shop.

May we tell you more about them?

Montreal, Que.
St. John, N.B., Vancouver, B.C.

WATCHING THE DETAILS

"In order to realize the full possible return upon the investment in machine tool equipment it is necessary that the capacity of the machines and the tools be carefully balanced and that proper jigs be provided to facilitate their operation to the practical limit. It is also necessary that power in sufficient quantity and in suitable form be available," says Ernest Cordeal, in a recent issue of Industrial Management.

"The small factory cannot have individual motor drive on all of its machines, but it may have well arranged groups driven by motors; or where the line shaft cannot be dispensed with, the speed of the shaft and the ratio of pulleys may be so figured as to permit each machine to operate close to its most efficient rate. There is no possible economy in saving on power equipment at the expense of an efficient drive. Motors in the small factory very frequently carry a heavy over-load, adequate power and simultaneous operation of all units being impossible. Belting is another matter which requires constant and competent attention. Belts of insufficient size, run at improper tension or not effectively cared for may easily dissipate between source and use sufficient power to make up the difference between efficiency and inefficiency."

LUBRICATION OF DRIVING CHAINS

An effective way of lubricating roller chains working in the open, or where dust and dirt are likely to be harmful is to use a solid lubricant, such as tallow, or one can use any of the various mixtures of solidified oil and graphite at present on the market. The lubricant, whatever its constituents, must be stiff—the stiffer the better—but it must not crack and flake off when the chain is under load. Before the lubricant is applied, the chain should be thoroughly cleaned in paraffin. The lubricant should then be melted and rendered quite fluid, after which the chain, placed on it, should remain in the oil for an hour or more. "After having been removed from the oil and hung up to drain," concludes a writer in Pratical Engineer, "the chain must be used as soon as the lubricant has set. In operation the lubricant is gradually squeezed out from the joints, and removes any grit that may accumulate. When all the lubricant has thus been used, the chain should be treated again. The chains of motor wagons and commercial vehicles, to which the above process is particularly applicable, should be treated once a week if the vehicle is in use every day."

A NEW AEROPLANE ENGINE STARTER

As in the case of the motor car, the starting of an engine on an aeroplane is a minor problem by itself. A British firm has solved it in a very simple way in the case of engines having six or more cylinders and developing up to 500 h. p. The apparatus consists of a small air-cooled single cylinder motor coupled to a pumping cylinder which draws combustion mixture from a carburettor and delivers it under pressure to the main engine cylinders. The mechanism is so arranged that the gas passes into each of the main cylinders. This auxiliary motor will maintain a gas pressure of 140 lb. per square inch, which is sufficient to turn the most troublesome engine. The weight of the starting apparatus is 40 lbs. complete. After the main engine has been started, the motor can be run continuously for any driving auxiliaries.

CARGO CARRYING AEROPLANES

A novel type of aeroplane is being constructed by a British company under the auspices of the British Air Ministry. It is designed mainly with a view to carrying capacity, speed being sacrificed to some extent in order to give more scope for cargo. Careful experiments will be made to decide certain disputed points about the actual cost of carrying goods by air. Aircraft enthusiasts hold that for long distances the cost of carriage by air will be very little in excess of road motor charges. The capacity of the machine will be three tons.

Classified Opportunities

FOR SALE

FACTORIES FOR SALE — TWO DESIRABLE plants; one at Mount Forest, constructed of brick, floorage over 40,000 square feet, formerly operated by Weir Wardrobe Co.; and the other at Guelph, stone floorage over 50,000 square ft., formerly operated by Dominion Casket Co. Apply Box 777G, Canadian Machinery.

BUSINESS CHANCES

WANTED—BY AN ESTABLISHED CONCERN. Twelve to fifteen thousand dollars for a period of from one to three years, to take care of business expansion. This concern will stand the fullest investigation. 8% is offered with ample security to principals only, with an opportunity of becoming permanent associates with the partners, if mutually satisfied. Hand Protection

Means Better Work

Mitten Style No. 681

Steel-Grip WORK MITTENS

and work gloves give complete hand **protection** plus hand **comfort.** The same reinforcement (small steel ribbons over strips of tough leather) that protects the hand also gives so much extra wear that these mittens and gloves last almost indefinitely. Sewed closed with steel thread, they are absolutely rip-proof. The steel reinforcement does not interfere with flexibility. Your workmen equipped with Steel-Grips will dig in with a will.

Write us to-day for suggestions on your hand protection problems. We can save you money on your work glove purchases.

BILLMONT WRENCHES

with Interchangeable Sockets

The "Master" Wrench

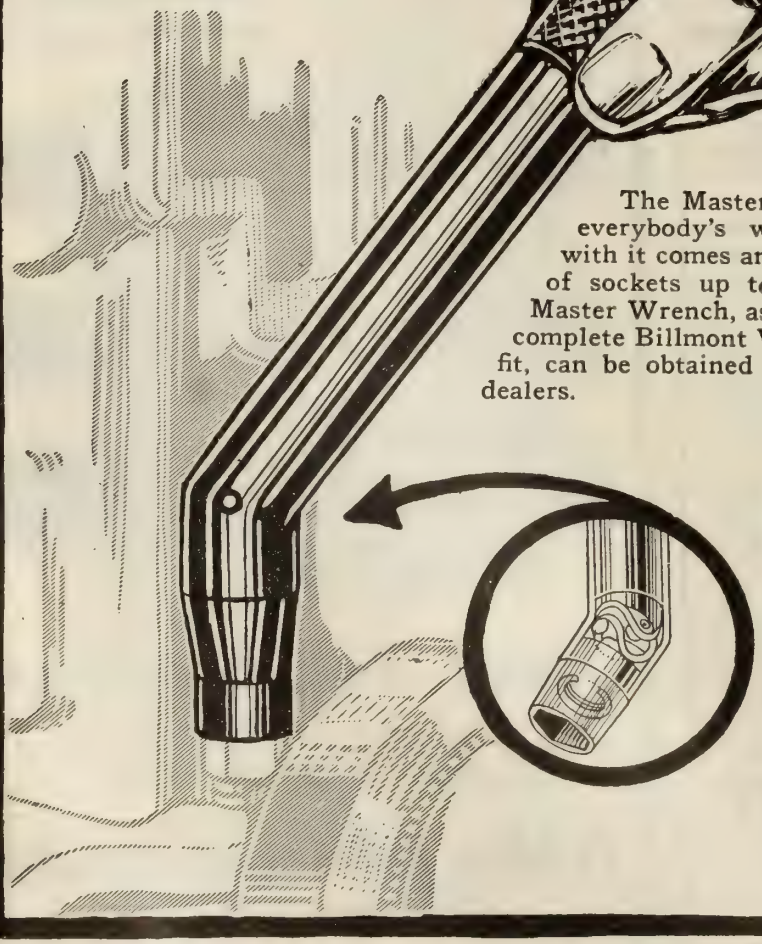
This wrench is a masterpiece among tools. With the strength of a pile driver, with its hooked nose and knurled hand grip, sliding handle, it is probably the most universal tool in the world.

No car, truck or tractor owner should be without one.

No farmer or mechanic should be without one. It is useful in every household.

This wrench gets in the most difficult places, where often you have to use a chisel and hammer to remove the nut. Hours of labor could be saved by having at hand the master wrench.

Ball and spring in cap keeps handle in place. The solid "T" bar handle which slides back and forth, in order to pass any obstruction, gives tremendous power.



The Master Wrench is everybody's wrench, and with it comes an assortment of sockets up to 1″. This Master Wrench, as well as the complete Billmont Wrench outfit, can be obtained at all good dealers.

Ask your dealer or write us.

Russell Gear & Machine Co., Ltd.

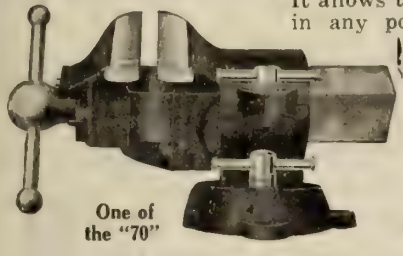
1209 King St. West

Toronto - Ontario

The Universal Billmont Nose-Piece

The nose, turned at an angle at the end of a long, straight shank, makes it possible to reach places that would otherwise be hard to get at. The outer tube is stationary and offers a firm grip. The universal nose piece takes sockets of all sizes.

PARKER VISES



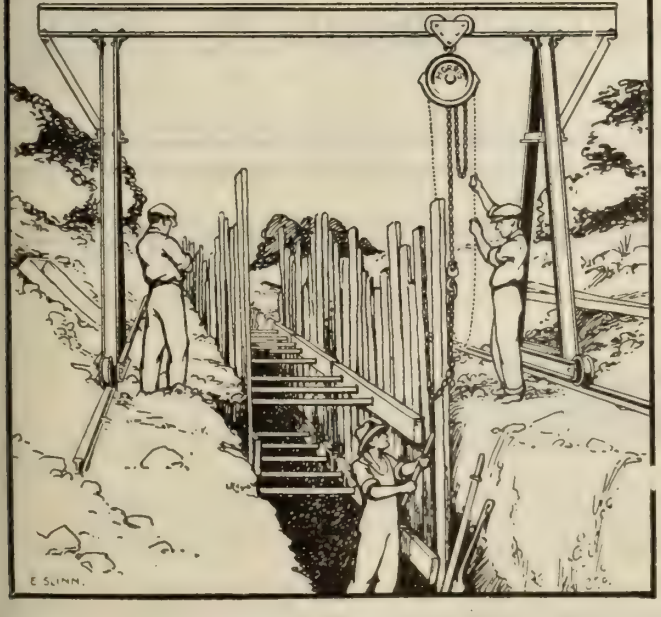
Have Renewable Jaws

They can be given a new "grip" on life in a few minutes, at a trifling cost. The jaws are of special tool steel, good for long service. But, if you should want to renew them, simply remove two pins and put in new jaws. This applies to nearly all Parker Vises, of which there are many styles.

They "GRIP LIKE A GRIZZLY"

Here's One With Double Swivel

One of the "70"



It allows turning the work in any position while in the jaws. Send for Folder No. 12 and get the whole story.

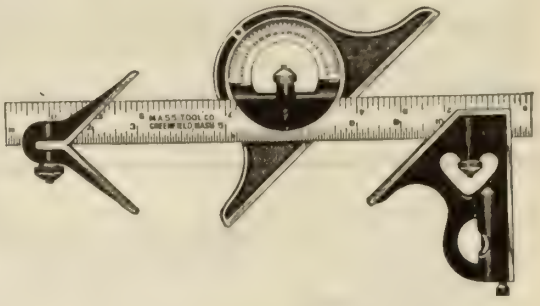
MORRIS CHAIN-BLOCKS



are popular among contractors because with all their qualities of speed, ease and safety, they are also rugged enough for rough handling.

THE HERBERT MORRIS CRANE & HOIST COMPANY, Ltd.
NIAGARA FALLS, ONTARIO

GOODELL-PRATT

1500 GOOD TOOLS

Try Before You Buy

Why buy precision tools blindly on reputation? Why not test each tool yourself before you buy it?

If it's a Square you want, test it out with another and make sure you get a light-tight fit.

If it's a Steel Rule, "mike" its length and get one that is correct.

If it's a Micrometer Caliper or Depth Gauge, check it every .010 inch with a set of blocks.

If it's a Feeler Gauge, measure the thickness of the leaves.

Goodell-Pratt Precision Tools welcome any test you want to make, because every one is made with good old-fashioned honesty and care. We don't ask you to take our word for it; all we ask is that you give Goodell-Pratt Tools a fair test.

Write for "Tools for the Toolmaker".

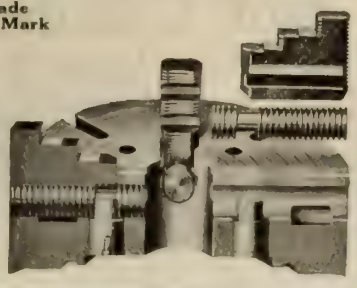
WHAT IS YOUR ADVERTISING DOLLAR BUYING?



High prices of materials and increased overhead have made necessary a stricter economy along mercantile lines.

Advertising should be considered as well as the commodities in which merchants deal. By choosing only those publications whose circulation is accurately measured, you not only practise economy in your advertising, but are assured that your money is buying a definite quantity of circulation.

Canadian Machinery's circulation is measured by the Audit Bureau of Circulation. Advertising placed in its columns is an economical investment.

SKINNER STEEL BODY INDEPENDENT CHUCK

Trade Mark

POWERFUL-STURDY-DEPENDABLE-ACCURATE

For production, where exceptional gripping power is required, where heavy cuts are often necessary and large pieces are held, this type of chuck will render most satisfactory service.

Although the Skinner Steel Body Chuck has been in use for years, we have never known of one breaking in service. It is the heaviest, strongest Independent chuck made.

Body—Cast Steel. Jaws—Extra wide. Adjusting screws—Large diameter.
Illustrated literature and catalogue on request.

THE SKINNER CHUCK COMPANY

NEW BRITAIN, CONN U S A — Established 1887

New York Office: 94 Reade Street, — San Francisco Office: Rialto Building — Chicago Office: 552 W. Washington Blvd.

London Office: 139 Queen Victoria St., E.C. 4.

Buried in the Work and Broke!

Next time a tap breaks below the surface of a large casting, don't let some makeshift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

Walton it Out in a Jiffy

And save the casting.

Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

Sixty-day trial offer proves the Walton Extractor pays for itself. Write.

The Walton Co.
Hartford, Conn.

Hoisting

is simplified by use of the Wright High Speed Hoist. An easy pull on the non-fouling chain produces a quick, steady lift at the hook, and then the positive safety lock holds the load at any desired height. Wright Hoists are sturdy and built to stand abuse. Try one.

Do you want more facts?

RENOLD
SILENT CHAIN DRIVE

More Power

Less Waste

The Recognized Standard for Efficient Power Transmission

Twenty-six years' highly efficient performance in the finest plants in the country has built up an enviable reputation for Renold Silent Chain Drives. Absolute reliability in service with maximum efficiency and minimum maintenance costs has made "Renold" the universal name for power transmission chains. Renold Silent Chain Drives are applicable to any powers, no matter how small or large and not only are they silent in operation, but also unaffected by heat, cold or moisture.

Let Renold Chains solve YOUR power transmission problems, and ensure YOU maximum efficiency, durability and service. Our engineering service is at your disposal without obligation. Why not write us?

"CUSHMAN" CHUCKS 1862

Known Everywhere

YOUR DEALER WILL FURNISH THEM

THE TRADE K—T IE MARK FOUNDRY GALT, ONT.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

"Real Sales Helps—PHOTOSTAT Prints"

With a PHOTOSTAT you can send your salesmen and agents facsimile copies of testimonial letters. You can send these on the same day they are received and in a size that will fit the salesmen's books. You can also send them copies of rush bulletins, clippings, catalog pages, explanations of new designs, laboratory reports, and other sales helps.

You can get these copies to the salesmen while the material is real news, because it only takes a few minutes to make a PHOTOSTAT print. Your salesmen will appreciate such co-operation.

In addition to furnishing sales helps quickly and at small cost, the PHOTOSTAT also has great value for the production department in making photographic facsimiles of pencil sketches, drawings, blue prints and even of small articles. Here the PHOTOSTAT eliminates the necessity of making tracings. The PHOTOSTAT copies directly on sensitized paper at original, enlarged or reduced size.

In the office the PHOTOSTAT eliminates the mechanical drudgery of copying by typewriter or longhand. It copies letters, telegrams, reports, graphs, charts, shipping lists, contracts, ledger pages, insurance records, legal documents. These PHOTOSTAT copies do not have to be read back for errors or checked with the original. You know they are right.

Just ask for a copy of our booklet, "The PHOTOSTAT and What It Will Do."

MODERN
Plain Grinding Machines

Main Drive

The shaft is ground, and mounted on anti-friction bearings; runs at constant speed. Power can be applied from a line shaft or direct from motor. All parts are balanced to eliminate vibration.

Wheel Drive

More powerful than other types of same rating. A 4-in. endless belt carries the full power from main shaft direct to wheel spindle, giving constant smooth drive.

Gear Case

All speeds and feeds are secured from one gear box, a separate unit, which may be readily removed for inspection or renewal of bearings. Gears are in mesh at all times, and are engaged with shaft by our patented positive ball drive clutch, which permits instant change. Gears of steel with hardened bushings run in grease.

Send Us

—Blueprints and specifications, and we'll tell you what a Modern will do on your job.

Motor Drive

A constant speed motor may be attached to the main drive shaft of the machine by belt, silent chain or flexible coupling.

All Modern Plain Grinders are specially designed for most convenient connection to motor.

Wheel Side

Travel is on "V" and "Flat" ways, giving true, accurate movements and long life. A gib prevents raising of slide when heavy cuts are taken.

Bearings

Wheel spindle has bronze bearings with outside taper. Quick take-up for wear without dismounting is provided.

Main drive has anti-friction bearings.

Headstock has ball bearings.

Gear box has phosphor bronze bearings.

All provided with proper lubrication.

All shafts are ground.

List of Directory of Dealers will be found above Advertising Index

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

Torrington

MACHINE SCREWS

Because the Quality is Above Average

—it is not meet to suppose that Torrington machine screws are higher in price than other machine screws.

When you link up with TORRINGTON, you are assured of products made by men of ripe experience who have made a special study of the line. Yet this guarantee of high-grade workmanship costs you nothing extra.

Rivets, Threaded Wires and Specialties

In addition to our well-known lines of machine screws we manufacture high grade Rivets, from Brass, Copper, Steel, German Silver and Aluminum. Also Threaded Wire and Specialties to meet all requirements.

And if our standard machine screws do not exactly suit your needs we are prepared to manufacture special screws at a moderate price.

Put your faith in Torrington—you'll never regret it.

May we send you samples of these Torrington Products?

READ AND PASS TO	Check	See Page	READ AND PASS TO	Check	See Page

Is your business efficiency four square?

TIME BOOKS, BRASS CHECKS, HUMAN TIMEKEEPERS force you to say:

"The PROBABILITY is that I am getting nearly all the Time I am paying for"

THE INTERNATIONAL TIME RECORDER will enable you to say with confidence:

"The *FACT IS* I am getting all the Labor Time I pay for."

TIME RECORDER PRICES BACK TO BED-ROCK

These reductions will range from $10 to $85, according to style and type of instrument. Effective immediately.

International Business Machines, Co., Limited

Frank E. Mutton, Vice-President and General Manager. HEAD OFFICE and FACTORY—Royce and Campbell Avenues, Toronto.
For your convenience we have Service and Sales offices in Vancouver, Winnipeg, Walkerville, London, Hamilton, Ottawa, Montreal, Quebec Halifax, St. Johns, Nfld.

Also manufacturers of International Dayton Scales and International Electric Tabulators and Sorters.

SMALL TOOLS

Pratt & Whitney Adjustable Blade Reamers

These reamers have eccentric relief and can be set to size without regrinding. They are unexcelled for design and simplicity and ease of adjustment.

The eccentrically relieved blades are stronger than others, do not chatter, and produce a smoother hole. The hand, shell and fluted chucking reamers have interchangeable nuts, screws and wrenches. The bottom of a hole can readily be faced.

By a simple adjustment of the blades the reamer can easily be set to size, without regrinding.

Prompt service is assured at our nearest store, where P. & W. Small Tools are carried in stock for immediate delivery. Place your order there to-day.

Why Not Utilize The Wall Space?

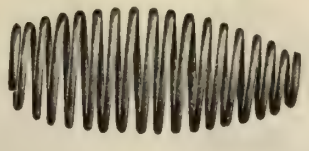
You are cramped for space; it looks as if you need to build—yet, there is space to use on your walls.

Dennisteel Shelving makes space for the storing of materials. It can be kept in systematic order, and does away with the necessity of a store-room.

Dennisteel Lockers do away with the necessity of a cloak-room, and offer your employees privacy and security for their personal belongings.

Dennisteel Products are Fire-resisting.

We also make:



Steel Cabinets, Steel Lavatory Compartments, etc.; Ornamental Iron and Bronze; Commercial Wirework of all kinds; General Builders' Ironwork; "Boca" Solid Steel Sash.

Price vs. Service

Just "because they're cheap" is no reason why you should buy cast Clamps and Lathe Dogs.

They're dear at any price if not dependable and no *cast* product can be dependable for such service.

Williams' lines of drop-forged tools will never fail you and will last a lifetime. They're all guaranteed.

CLAMPS—11 patterns, in a wide range of sizes for every purpose.

SAFETY LATHE DOGS, Straight or Bent Tail, 1 or 2 Screws, 16 sizes.

DROP-FORGINGS
often cheaper than castings
—always far superior—

Valves on Dominion Oxygen Cylinders Do Not Leak

WHEN you order a tank of Dominion Oxygen, you get a cylinder filled to capacity—just the way it left the plant. There are no leaking valves dissipating oxygen into the air instead of conserving it for efficient welding and cutting at the blowpipe's tip.

The wedge valve on a Dominion Oxygen cylinder has been perfected in design and construction after years of careful study. It is your assurance of a full tank and no waste. Forged from bar stock, it resists the wear of internal friction and reseats itself while the tank is fully charged and in use—truly a money-saving feature.

This non-leaking valve is only one of the many evidences of the good service rendered by Dominion Oxygen to its customers.

To secure uniformly pure oxygen in lightweight cylinders with efficient valves, shipped to you the same day that your order is received, order a sample cylinder today from our nearest Distributing Station.

Our price is right. Our service is right—be sure to let us quote you before ordering your supply, and you will be sure of getting the best possible prices and service obtainable.

Was the New Cabinet Made in Montreal?

THE SECRET of the Cabinet is out. J. K. Munro, whose observations on what goes on behind the scenes in Ottawa have amused, entertained and instructed readers of MACLEAN'S in recent years, "explains" what happened when Premier Mackenzie King endeavored to pick his own Cabinet members.

Of course you will want to read this "inside" story of Canadian politics in

MacLean's Magazine
for
February 1st

which is on sale at all news-stands to-day.
This issue also includes several timely and authentic articles on subjects of national importance to Canadians, as well as a particularly attractive list of entertaining fiction, and a generous measure of Reviews.

Here's the "Inside Story"
According to Mr. Munro:

"Crerar had read the King proposals to his Western Progressives assembled at Saskatoon, and had so far received their approval that he was on his way East, presumably to close the deal.

"Then something happened. Sir Lomer Gouin and Senator Dandurand are represented as visiting Ottawa and turning the Liberal leader's plans topsy-turvy." Mr. Munro goes on to say: "The Cabinet slate had been smashed. . . . . A different reception had been prepared for the Hired Man's Hero. . . . . What did the little Quebec Boss do in those three hours? Well, report says that he went straight to the Rideau Club, where the young Premier-to-be was waiting for him in the 'Silence Room' (that said silence was so rudely shattered that a frightened waiter crept up and closed the door); and that behind that closed door an embryo statesman had it made plainly evident that the powers that made could unmake; and that a Quebec that had given him a sullen support would rise and rend him unless he listened to her voice—and Sir Lomer had Quebec's voice about his person."

READ THESE FOR INFORMATION:

THE WEST WON'T STAY DOWN—by Charles Christopher Jenkins: The second of two up-to-the-minute articles showing how the Canadian West is meeting its various agricultural, financial, economic, commercial and social problems in these days of stress and strain.

FAR NORTH REALLY LIVEABLE—by Vilhjalmur Stefansson: Canada's foremost Arctic explorer gives facts and figures to prove that life in the Land of Winking Night can really be pleasurable and profitable.

THAT MAN FROM CARSTAIRS—by Nicholas North: A breezy, informative sketch of Henry Wise Wood—formerly "That Man from Missouri"—who wields such a potent influence in Albertan politics.

SLEUTHS OF THE WILDERNESS—R. G. MacBeth: A series of fascinating—and true—tales of Canada's famous red-coated force, and how offenders are tracked for months and years, by the Dominion's relentless, tireless preservers of peace in the wilds.

AND THESE FOR ENTERTAINMENT:

A PRIMROSE AND A PROMISE—by Margaret Busbee Shipp: A light little love-story which commences on a continental train, progresses through the tulip hills of Holland, and culminates in an international hockey match.

THE SAIL-DRAGGER—by Frederick William Wallace: A melodrama of the sea; which includes a pretty typist, a brawny hero, half a dozen Bolsheviks and a mysterious will,—all the ingredients of a fascinating "thriller."

HOW "BOB'S MAGGIE" GREW INTO HER JOB—by Ethel M. Chapman: The fascinating and adventurous life-story of Dr. Margaret Patterson, Toronto's new Police Magistrate.

ON THE JOB—by Archie McKishnie: "The Swallow" decided to go straight, but found many influences endeavoring to force him once again into the influences of the underworld. Mr. McKishnie, as usual, has a strong "twist in the tail" in this yarn.

MOSTLY SALLY—by Pelham Grenville Wodehouse: Some more about Sally and her fortune, and Ginger and his foibles.

THE HOUSE OF APPLEDORE—by "Sapper"—H. C. McNeile: "The Writer's Story": how a journalist was imprisoned, how he faced death, and how he used a clever code to escape.

ODETTE ELOPES—by Margaret Hilda Wise: A simple little tale, entertainingly told, of a girl who announced her elopement.

Besides all of this, the **Review of Reviews Department** gives a review of world-wide matters of current interest that alone is worth more than the price of the magazine.

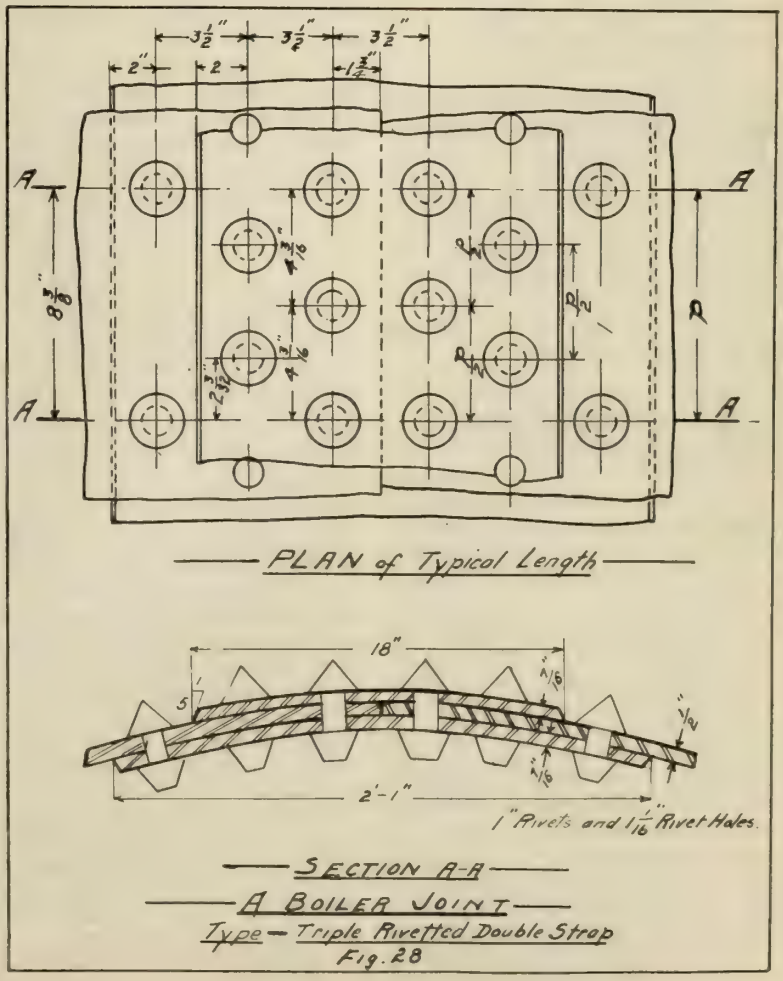
The Designing of a Triple Riveted Butt Joint

Factor of Safety Must Be Allowed—Determining Proper Thickness of Boiler Shell Plate—Strength of Boiler Shell—Sketching Proposed Joint—Resistance Against Tearing and Crushing

*By L. T. RUTLEDGE

THE STEEL to be used in the joint spoken of in the previous article in the January 26 issue, should be tested in a testing machine in order to determine its ultimate tensile, shearing and bearing values, and the value of the elastic limit for each kind of stress. The following are average values for the ultimate strength of ordinary boiler plate: in tension 60,000 lbs. per sq. inch, in bearing 90,000 lbs. per sq. inch, and in shear 45,000 lbs. per sq. inch. In boiler design a factor of safety of not less than 5 should be used; this being the usual factor employed.

Example:—It is required to design a triple riveted double strap, butt joint for a boiler 66 inches inside diameter, the maximum boiler pressure being 160 pounds per square inch. It is required that the joint be at least 85 per cent efficient.



Solution:—The first step will be the determination of the proper thickness of boiler shell plate. The boiler is a hollow cylinder, in the walls or casing of which stresses are induced by the internal pressure. The internal pressure is transmitted undiminished in all directions, and acts with equal intensity on all equal surfaces and at right angles to those surfaces. We assume that the stresses resulting from the external forces are distributed uniformly over the cross-section of the boiler shell.

Strength of Boiler

We shall consider the strength of the boiler shell in two main directions, namely, longitudinally and circumferentially. The longitudinal stress is caused by the pressure acting on the end of the cylindrical boiler, tending to tear the shell transversely. For a state of equilibrium the bursting external force must equal the internal resisting stress. The bursting force is given by the area of the cylinder end multiplied by the unit pressure, that is

$$\frac{\pi}{4} D^2 P$$

Where D is the internal diameter of the boiler, and P the internal pressure in pounds per square inch. The area that resists the bursting force is the area between two concentric circles, one D inches diameter and the other D+2t inches in diameter. This area is practically the area given by multiplying the circumference D by t. The unit stress is St. Thus the total resistance

PLAN of Typical Length

SECTION A-A

A BOILER JOINT

Type — Triple Rivetted Double Strap

Fig. 28

*The author is Professor of Mechanical Engineering at Queen's University, Kingston, Ont., and should any reader wish help in any problem on mechanical matters, Mr. Rutledge will be only too pleased to offer assistance. To save time, write direct to Kingston, explaining your trouble in detail.

is Dts. Now as stated above, for equilibrium

$$\frac{\pi}{4} D^2 P = \pi D t S$$

$$\text{Therefore } t = \frac{PD}{4St}$$

Next, let us consider the strength of the boiler in a direction at right angles to the above. The bursting force, in this case, is that which tends to lift one half of the boiler longitudinally from the other half. The bursting force is given by the expression PDL where L is the length of the boiler inside. Although the inside surface is a semi-circle in one direction, it is quite correct to consider the resulting pressures as those at right angles to a plane through the centre of the circle; the plane being the one passing through the sections of the shell where it resists the bursting force.

The area that resists the load consists of two rectangles, each t inches in thickness and L inches long, the two sections being 180 deg. apart. The resisting area is 2 Lt. The total resistance is

$$2Lt\,S_t$$

For equilibrium

$$PDL = 2Lt\,S_t$$

$$\text{Thus } t = \frac{PD}{2St}$$

It will be observed that this latter formula gives a thickness twice that given by the formula first obtained. This shows that if a boiler fails, it is altogether certain to fail along a longitudinal seam. So, for purposes of design and for safety, we shall use the latter formula, which gives the greater thickness.

Then, using the data given in the problem as stated, we have

$$t = \frac{PD}{2St} = \frac{160 \times 66}{2 \times 12000} = .44 \text{ ins.}$$

We use a factor of safety of 5; hence 12,000, being one-fifth of 60,000, (the ultimate strength of the boiler plate in tension) is the working tensile strength of the joint.

The boiler joint cannot be 100 per cent efficient. We are only required to make it 85 per cent efficient. This means that the joint is 85 per cent. as strong as the solid unpunched plate. So if we use the above value of "t" and have our joint 85 per cent. as strong as the clear boiler plate, it is apparent we shall not have a factor of safety of 5 in our boiler design as the joint will lower its value. The strength of the boiler is no stronger than the joint. Now, if we wish the joint to have a factor of safety of 5, let us make the plate thicker. If we consider 0.44 inches as 85 per cent. of the thickness to be used and find what thickness would be 100 per cent. then we have fulfilled the condition as regards the factor of safety.

Therefore the thickness to be used in the design is

$$t = \frac{0.44}{.85} = .50 \text{ ins.}$$

We shall, then, specify ½ inch boiler plate, which happens to be a commercial size.

The cover-plates or straps of a triple riveted butt joint for ½ inch boiler plate will be 7/16 inch, according to tables of standard practice as given in handbooks. The diameter of rivet that would be consistent with the thickness of plates to be used is 1 inch. Thus we shall assume $t' = 7/16$ in. and $d = 1$ in.

The diameter of the rivet hole; $d' =$ 1-1/16 in. The above assumed value shall be tested in the following solution, in order to ascertain if the assumptions are correct.

In the example, the following permissible working stresses obtained from the ultimate values by adopting a factor of shaft of 5 will be assumed:—

Tension 12000 lbs. per sq. in.
Bearing 18000 lbs. per sq. in.
Shear 9000 lbs. per sq. in.

The foregoing values are good average ones for boiler steel. In most cases the values are somewhat greater.

A sketch of the proposed joint should now be made, which sketch is quite similar to the illustration in Fig. 28. There will be three rows of rivets on each side of the butt joint and it is assumed at the beginning that the cover plate on the outside of the boiler does not have to be as wide as the inner plate since the pitch of the rivets in the outer row is made twice as great as in the middle and inner row.

The results given by the various calculations for strength will indicate if this is a correct design or not. Hence if the joints fulfill the specifications there is no reason to make the butt straps of equal width. Assume "P" to be the pitch between two rivets in the outer row. A typical length of joint on which to make the calculations will be that between the two similar sections marked A—A. The adjacent lengths are exact duplicates and similar for the entire length of the boiler.

In the analysis of the joint it is best to consider and determine the resistance against every possible failure in the typical length of boiler joint.

The various resistances against failure are:—

1. Resistance against tearing of the plate in the outer row:—

Using the previous notation, we have the resistance against this failure to be

$$P_1 = (p - d')\,t\,S_t \text{ ---- (a)}$$

Where $(p\text{-}d')$ is the length of solid metal between two adjacent rivets.

2. Resistance against tearing of the plate between the rivet holes in the second row combined with the failure of the rivet in the outer row, the rivet in the outer row falling either by shear or by crushing against the cover plate:—To express this correctly we need two algebraic equations, namely,

$$P_2 = (p - 2d')\,t\,S_t + \frac{\pi d^2}{4} S_s \text{ ---- (b)}$$

$$P_3 = (p - 2d')\,t\,S_t + d t' S_b \text{ ---- (c)}$$

In the equations just established, it is well to note the first term. In the second rivet row in our typical length of joint between sections A—A two rivet holes occur. These are shown deducted in the equations.

3. Resistance against shearing of all the rivets:—In our typical length of joint on the one side we have in the second and inner row four rivets in double shear and one in the outer row in single shear. The total of these is equivalent to nine rivets in single shear, therefore

$$P_4 = 9\,\frac{\pi d^2}{4} S_s \text{ ---- (d)}$$

4. Resistance against crushing of all the rivets:—The joint may fail by the crushing of the four rivets of the second and inner row against the boiler plate, and the crushing of the rivet in the outer row against the cover plate. Then the resistance against this probable failure is

$$P_5 = (4t + t')\,d\,S_b \text{ --- (e)}$$

5. Resistance against combined crushing and shearing. The joint may fail by the crushing of the four inner rivets and the shearing of the rivet in the outer row. For this we have

$$P_6 = 4dt\,S_b + \frac{\pi d^2}{4} S_s \text{ --- (f)}$$

A joint of this type should be designed so that it becomes stronger as the center line of the joint is approached. This condition is obtained by making equations (b) and (c) greater than (a) that is

$$(p - d) < \frac{t}{S_s p \pi} + \frac{\pi}{4} t (p\pi - d)$$

$$t S_t \text{ and } (p - 2d')\,t S_t + d t' S_b > (p - d')\,t S_t$$

For simplicity in this case, where absolute accuracy is not essential, assume d' equal to d, then by simplification of the above expressions we see that the condition is obtained if

$$d > \frac{4tS_t}{\pi . S_c} \quad --- (g)$$

which verifies our assumption for value of d in the first place and from the second expression we find that

$$t' > \frac{tS_t}{S_b} \quad ---(h)$$

The algebraic solution is completed. At this point we might insert arithmetical values in equations (g) and (h). Thus d must be greater than

$$4 \times \tfrac{1}{2} \times \frac{12000}{3014 \times 9000} \text{ or } .85 \text{ inch.}$$

Therefore a one inch rivet is satisfactory.

Also t' must be greater than

$$\tfrac{1}{2} \times \frac{12,000}{18,000} \text{ or } .33 \text{ inch.}$$

Therefore a 7/16 inch cover plate satisfies the condition.

The problem is to find the value of the pitch "P." To do this, determine the resistances of P_4 P_5 and P_6 as given by equations (d), (e) and (f)

$$P_4 = \frac{9 \times 3.14 \times 1^2}{4} \times 9000 = 63617 \text{ Lbs.}$$

$$P_5 = \left(4 \times \tfrac{1}{2} + \tfrac{7}{16}\right) 1 \times 18000 = 43875 \text{ Lbs}$$

$$P_6 = (4 \times 1 \times \tfrac{1}{2} \times 18000) + \frac{3.14 \times 1^2}{4} \times 9006$$

$$= 45088 \text{ Lbs.}$$

The minimum value is that given by P_5, namely, 43,875. Equate P_1 to this value in order to determine the quantity "P."

$$43875 = (p - d')t\,S_t \text{ or}$$

$$43875 = (p - 1/16)\tfrac{1}{2} \times 12000$$

$$\text{therefore } p = 8.36 \text{ or } 8\tfrac{3}{8} \text{ Approx.}$$

Therefore P=8.36=8⅜ approx.

We shall use the value 8⅜ but before adopting it finally, we must determine the values for P_2 and P_3 with P=8⅜. On substitution in equations (b) and (c) we get

P_2=44,568 lbs. and P_3=45,375 lbs.

It will be observed that the resistance as given by P_4 and applied to P_1 is the minimum value, the value being 43,875 lbs.

The efficiency of our joint as designed is equal to the minimum resistance or the strength of solid plate of length equal to pitch.

$$= \frac{43,875}{8\tfrac{3}{8} \times \tfrac{1}{2} \times 12,000} = \frac{43,875}{50,250} = .876$$

Thus the efficiency is 87.6 per cent. which is a little higher than the specifications called for.

The detail of the joint may be completed as shown in Fig. 28. The position of the gauge lines should be clearly dimensioned. The long pitch is 8⅜ins., the short pitch is 4-3/16 ins. The back pitch should be about 70 per cent. of the short pitch. This is given as 3½ ins. For boiler work, the marginal distance should be 2ins. where 1-inch rivets are used.

Suggested Problems

1. Determine the pressure that may be safely carried in an air receiver 60in. in diameter, the shell of which is ⅜in. thick. The longitudinal seam is of the triple-riveted butt joint type having two 5/16 in. cover plates. The rivets are ¾in. in diameter and the pitch in the outer row is 6½in. The back pitch is 2-7/16in. and the margin is 1-7/32 in. The permissible working stresses for tension, shearing and bearing are 12,000, 8,800 and 19,000 lbs. per sq. in. respectively.

2. A pressure tank 48in. in diameter is subjected to an internal pressure of 150 lbs. per sq. in. Design a double riveted lap joint for the longitudinal seam of the above tank assuming the same working stresses as given in problem 1.

PORTABLE CRANE

A new industrial portable crane has been placed on the British market recently. This crane is electrically operated and can run in and out through the doorways of warehouses and stockrooms and can be placed alongside a motor truck or railway car, that requires to be loaded or unloaded in the shortest space of time. It has a jib type of crane which is mounted on a "runabout" chassis, without the usual turntable arrangements. That is to say, that the crane is rigidly attached to the chassis and always remains in the same relative position to it. Motive power is supplied by storage batteries to electric motors. The two steering wheels can be turned so that the whole crane will revolve by power about its own axis without any motion of translation. The capacity of the crane is 1,500 pounds, at a radius of ten feet in any position in the circle, with a height of hook of twelve feet. The crane is guaranteed to sustain an overload of 25 per cent. The overall width of the apparatus is six feet. It rotates in a circle of 6 feet 3 inches in diameter. The weight, including the drive, is about three tons. The crane can travel at a speed of about 300 ft. per minute and will hoist at a speed of twenty feet per minute, and slews at the rate of 2½ revolutions a minute.

The overhead clearance when the jib is lowered into a horizontal position is such that it will pass under a 7 foot 6 inch doorway. The weight is so disposed that with the jib fully loaded, and in any position, the maximum weight on any one wheel never exceeds one ton. Provision is made to enable the apparatus to become a tractor and it will draw a load of 3 tons at the rate of three miles an hour. The crane is equipped with a storage battery of sufficient capacity for an average day's work. This battery is of 258 ampere hours capacity.

The runabout crane truck is manufactured by Messrs. Ransomes, Sims & Jeffries Limited, Orwell Works, Ipswich, England, and the crane mechanism is the production of Messrs. Ransomes & Rapier Limited, also of Ipswich, England.

AIR OPERATED JACK

An automobile jack operated by compressed air is useful in factories and garages where compressed air is available. Such a jack is now being made, and an 18 in. hollow handle connects a cylinder at the bottom, this extending up at an angle of about 30 deg. At the end of this handle are located an air cock and a hose connection. The piston is of the leather-cup type.

This jack, is made in two sizes, 6 in. and 8 in. The 6-in. jack has a piston head area of 28¼ sq. in., and, with an air pressure of 100 lb. per square inch, will lift 2,825 lb. The 8-inch jack has a piston head area of 50¼ sq. in., and, with 100 lb. air pressure, will lift 5,250 lb. By attaching a standard air gage with special dial graduations to the cylinder of the jack the latter may be used as a weighing device, indicating directly the weight on the tires. The particular advantage claimed for this type of jack is quickness of operation. It is said to take only five seconds to raise a car off the floor. The Avery Engineering Co. is the maker.

FLAME OF HIGH TEMPERATURE

A flame of extraordinarily high temperature has been employed in experiment by E. Hauser and E. Rie, this being mentioned in the Chemical Trades Journal. This flame is produced by liquid fuel, which is led by a tube from a storage container to a special burner, where it is atomised, and forced out into a horizontal cone by a stream of hydrogen or other suitable gas, and combustion is intensified by a mantle of oxygen enveloping the cone from the outer part of the burner. It is estimated that the temperature reached is at least 3,000 deg. Cent.

The Danger of Wear In Machine Tool Parts

Main Bearings Require Careful Attention—Watch Lubrication—Prevent Binding—Wear in Feed Screws—Emergency Devices to Overcome Effects of Wear—Indexing on Turret Lathes

By H. A. WILSON

THE DEVELOPMENT of modern machinery has progressed by leaps and bounds during the last century. During that period countless difficulties have been encountered and many have been overcome. Since the beginning of time, however, we have never really been able to overcome the disastrous effects of wear. Through the mediums of experimenting, research, and careful designing the effect has been reduced to a minimum, but always wear occurs in the most vital parts of a machine, such as in bearings, slides, feeds, nuts, gear trains, etc. The functioning of any machine is entirely dependent on the proper application of power and subsequent restriction of motion of the component parts. As soon as power is applied and motion of the parts occurs, the movement of these parts must be controlled if useful work is to be performed. In controlling this motion the moving surface of one part of the machine must rub against another, and of course, wear commences. The greater the pressure per unit of area, the greater the wear.

If two pieces of dry metal, with machine finished surfaces were rubbed together, the friction would be very great, and some form of lubricant has been used since primitive times to lessen the friction and reduce the power required to cause the pieces to move over one another. Thus we can feel tolerably certain that one of the first attempts to minimize the effect of wear was to make use of some form of lubrication.

Effects of Wear

To come to the present time and study the effects of wear and the attempts made to overcome it, we will consider a modern engine lathe. First, the main bearings. These are very rugged and of liberal dimensions as the strains of modern lathes have been increased for high speed tool steel has manifested its ability to stand up under heavier cuts at ever-increasing speeds. The large area of these bearings has a direct effect on their life. The lathe spindles are usually hardened and the journals ground. The bearings are lined with a good grade of brass, or bronze, and in some cases a first class babbitt, or even gun-metal liner is found. As the spindle is ground and has previously been hardened, it is not at all probable that any wear will occur here, but the linings of the bearings, being a softer metal, will wear.

The complications that follow worn bearings in an engine lathe, are many. There is no class of work that can be accurately machined if loose bearings exist. Another source of trouble caused by loose and worn bearings is chattering of the tool. Of course chattering has many sources of origin, and may occur with the main bearings in first-class condition, but work cannot be turned straight, it will not be round, and it cannot be faced square if worn bearings exist. If the designer has placed liberally dimensioned bearings on a lathe, there still must be given to these bearings, proper attention, if the wear is to be kept down to a minimum.

Lubrication Important

Proper lubrication is essential. A bearing will not be able to remain in good condition if it is overloaded and run at speeds beyond which it was designed to operate. Oil holes should be cleaned out at reasonably short intervals and any old and gummy oil removed. It is also a good plan to occasionally wash the journals and liners with gasoline or kerosene. The means used to take up the thrust on a lathe should have proper attention, because if this unit is neglected, wear will occur and it will be extremely difficult to handle certain classes of work, such as shoulders, etc. There will undoubtedly be a little end play in the spindle which will have a habit of permitting the tool to "dig in" on a finish facing cut or some other similar important operation.

Of course this is more liable to occur when work that is held in a chuck, or bolted to the face plate without tail stock support, is being machined. When a piece is handled on a mandrel and end-play exists in a lathe spindle, the thrust is bound to be taken up by parts not designed to function in that particular manner, and additional wear of these parts occur. At the same time extra power is required to operate the machine, which may, or may not, tend to stretch the belt driving it. A machine operated under these conditions will rapidly become worse, as wear, in the parts called upon to take care of strains and stresses for which they were not designed, will be excessive.

Passing from the spindle we will consider the effect of the saddle sliding on the ways. The surfaces here in contact with one another are usually large, and pressure between these surfaces, in pounds per square inch, is not great. But the ways usually catch a fair proportion of chips and cuttings, which, if not watched, will soon cause disastrous wear. A large number of modern lathes have felt wipers attached to the saddle which are fairly effective in brushing away chips and lubricating the ways. Most of the pressure is taken up by the "V" slides, which to a great extent shed the chips. To prevent the saddle from lifting, guides are found under the side of the ways or in the apron. Sometimes there is some slight adjustment to compensate for wear at this point, and as practically all lathe saddles are actuated through screws or splined rods passing under the apron, the pull is on one side of the saddle which causes a slight additional strain and wear on the saddle and ways. Thus, to prevent binding, a pretty snug fit must be maintained at all times.

Should a saddle be worn, or the ways on the bed be in a bad shape, it is impossible to produce accurate work on the lathe. The majority of work is done near the head stock end, and in the case of a lathe that has seen considerable service it will invariably be noticed that when the saddle is adjusted so as to slide evenly and snugly, near the head stock end, it will bind when it is moved to the tail stock end, making it impossible to accurately turn a job of any great length. The wear of the tail stock on the ways of a lathe is negligible. However, the practice of turning, away from the head stock, on all work machined on a mandrel, causes the tail centre to take up the thrust, and excessive wear occurs here, which tends to produce inaccurate work. Whenever possible it is good practice to do all turning toward the head stock end as provisions have been made to absorb all end thrust created under these conditions, which is not the case when turning toward the tailstock.

Prolonging the Life

In the high class lathe of to-day, many measures have been resorted to, to prolong the life of the ways. In some cases a form of chilling has been employed when they are cast. This measure, of course forms a closer grained iron of a harder nature that resists wear to a greater extent than the ordinary softer castings made of grey iron. Some manufacturers melt a certain percentage of steel with the iron and produce what is commercially known as semi-steel castings. These castings are also closer grained and more wear resisting than ordinary grey iron, and are made from ten to fifty per cent. steel. Semi-steel is more easily machined than chilled cast iron, which is a feature that must be taken into consideration when large surfaces of the castings are finished, as in the case of a lathe bed. The motion of the tool slide and the compound rest is a comparatively small one. However, to offset the wear in dove-tail slides, jibs have been provided. Inaccuracies in the work and chattering are results of wear in these parts. There is never any excuse for wear in these parts as it is only

small, and the jibs enable it to be taken care of effectually.

Probably wear in the various feed screws in the lathe cause more concern than in any other part. This wear is always there, and slack or lost motion is commonly termed "back-lash." There is no real way of compensating for this wear and it has to be guarded against with extreme caution. However, when wear is evidenced in such parts it is not impossible to obtain accurate work, as a good mechanic can always keep the back lash where he wants it, and this does not let it interfere with his work. However, this wear should be avoided. Wear in the friction feed mechanism in the apron can be kept within reasonable limits if intelligent care is given the parts. The quick-change gears, and back gears do not present serious problems from wear.

The step cone pulley revolving on the spindle will be a continual source of trouble if not kept properly lubricated. Wear will then result which, perhaps may not have any direct effect on the accuracy of the work produced, but will prove a source of trouble, as there is a tendency to run dry and seize. The troubles and dangers arising from wear in a lathe, are to a certain extent common with several other machines. The milling machine spindle operates on a similar principle to that of the lathe spindle, and many similar comparisons could be made.

In passing, perhaps a reference of interest can be made to one or two emergency devices used to overcome and circumvent the effects of wear. A few years ago when lathes were almost impossible to obtain, many old and decrepit machines were pressed into service, for machining shell projectiles. Some lathes that would not turn true within wide margins, were fitted with chucks which screwed on the live spindle and extended out from the main spindle bearing from twelve to sixteen inches. The outer ends of these chucks were turned, and steady rests of sturdy design were placed to carry the overhanging end. These rests were of varied design, some having a three point contact consisting of adjustable brass blocks, others had full circular contact and were babbitted. This expedient overcame the results of the wear in the spindle and bearings and enabled the work to be turned fairly true. Some of these machines had been previously discarded and were again placed in service. Creditable work was done by these lathes although no work requiring extremely close limits, was attempted.

During this same period it was extremely hard to obtain steel for large lathe spindles. Many manufacturers turned to cast iron lathe spindles, of hollow design for special purpose lathes, and these were made extremely large in diameter at the front bearing. Collets were placed in the machine bore of spindles, holding shells right inside the front main bearing. These bearings were babbitted, but were of such large dimensions that the wear was practically nothing.

Use the Best Materials

In all class of automatic machinery, the bearings, journals, and all wearing parts have to be of liberal area and constructed from the best materials. These machines usually operate at high speeds and with only the intermittent attention of a skilled mechanic, any undue wear would be magnified through many inter-connecting mechanisms, which would result in an error in the work which might cause same to be useless for the purpose for which is was intended. In the case of a turret lathe where tools are carried on extending bars, if wear occurs in the indexing mechanism it usually has very bad results. This is easily explained. The indexing apparatus may be located 10 inches from the centre line around which the turret revolves, and the tool may be 25 inches from this point, thus the error would in such a case be magnified two and one half times.

Example after example of standard, automatic, and special machine tools could be taken in which wear would always cause inaccurate work to be produced. Lubrication should always be attended to, machines should be kept clean and speeds, feeds, and loads, should always have intelligent consideration. A mechanic should also know of a few of the fundamental points about the load per square inch certain classes of bearings can carry, that certain types require heavy oil, other bearings light oil, and that grease is sometimes better than oil on an oscillating joint. That babbitt bearings won't take an oscillating or reversing motion, that a soft steel bearing will not permit a soft steel journal to revolve in it, that cast iron makes an excellent emergency bearing for steel, etc.

Many of the light classes of machine tools to-day are equipped with ball bearings. Ball bearings are much more efficient from a mechanical point of view, than are the ordinary type. During the last few years much scientific investigation has been made, and to-day these bearings are giving excellent satisfaction on reasonably heavy work. Roller bearings have been designed to take care of heavy loads, and one big feature of both these styles is the ease with which they are lubricated. Light to medium heavy greases are used and a bearing once packed with such a lubricant is able to give service over a long period without further attention. The design of both ball and roller bearings being of the enclosed type, dust and other foreign matters do not easily find their way into the bearings. For this reason grinding heads, tool and cutter grinders, in fact many types of lighter machinery are equipped with ball and roller bearings.

Question of Thrust

When thrust bearings are considered, perhaps there is no better type for light and medium duties than ball thrust bearings. In drilling machines, lathes, tapping machines, grinders, etc., etc., thrust bearings play an important part. Perhaps it would be impossible to consider cutting tools as component parts of a machine tool. Taps are always designed with a land, which permits of re-sharpening until the land has been ground away, without altering the size of the tool. This practice also applies to reamers, milling cutters, circular form milling cutters, hobs, gear cutters and a multitude of other tools. The sharp edges are bound to become dulled in service and to continue to get good work the tools must be sharpened. Great care must be exercised in withdrawing from service any tool on which the land has been ground away. Unsatisfactory results will surely occur, as sizes can not be maintained.

Wear is a very serious feature in tool and cutter grinders. These machines are usually employed to finish to size, tools, cutters, gauges, and standards that will be used to produce, and check the accuracy of work turned out in large quantities. A slight error due to wear in one of these machines, would often be reflected in the manufacture of pieces produced in the plant. Thus great care must be exercised when looking after the bearings on these grinders. In fact this remark is quite applicable to any machine tool employed in a tool room.

The larger types of grinding machines have many special features incorporated in their design to reduce wear. Take for example machines used to grind rolls for paper machines. These rolls are large pieces, of no small weight, yet accuracies measured in thousandths and ten thousandths of an inch are required. Inverted ways are used, and these are continually flushed with cutting lubricants to wash away all grit. If one of these large and expensive rolls is inaccurately ground, even to the extent of the close measurements referred to above, it is useless, and an expensive piece is ruined. This shows how dangerous and expensive it would be to permit even the slightest wear to occur on such machines.

The whole subject simmers down almost to one of bearings, because it is in bearings that about 99 per cent. of the dangerous wear occurs. Perhaps all machine shops have not made extensive researches into the bearing problem. Yet, good mechanics know how to care for bearings and other machined parts exposed to wear. Lubrication is a first essential. This should be attended to by administering the proper lubricant at proper intervals. Dust should not be allowed to collect on machines particularly if this dust is of a gritty nature, and likely to possess abrasive qualities.

Oil spilled on machines or bearing housings attracts dust and grit, and if allowed to remain, part of this accumulation will invariably find its way into the bearings.

Hammers, cold chisels, tools, jigs and fixtures should not be placed on the finished ways of a machine, or in fact on any machine finished surface. Tapping with a steel hammer on any machined surface mars it. Only too often drills and reamers being placed in or removed from collets, sleeves and chucks are abused by the free use of a forged steel hammer. Chucks, collets, and sleeves become burred and this really is a form of wear, which all tends to produce inaccuracies in completed work. In concluding we will reproduce an article prepared by Messrs. R. O. Sperry and C. H. Landon, two gentlemen who have for years been connected with the engineering department of the American Bronze Corporation, a firm which has specialized in the field of scientific research in connection with wear in bearings. The plant and organization, with which they are identified, has been built up, and is being sustained, because of the fact that there is "Danger in Wear of Machine Tool Parts." Let them speak for themselves.

Design and Material Should be Watched Clo

By R. O. SPERRY and C. H. LANDON

THERE is at the present time a growing consciousness of the importance of a thorough understanding of the principles involved in the selection of bearing materials and of appropriate bearing design. This condition is manifested among engineers in genearl and especially among those responsible for the design of machine tools and automotive units. It applies particularly to the so-called plain bearings as the manufacturers of anti-friction bearings have supplied every comprehensive information covering these types during the past few years.

Plain bearings, while the oldest type known, are perhaps the least known. By this it is meant that a plain bearing is customarily considered simply as a bearing and there is very little accurate knowledge extant regarding the possibilities, range of usefulness and limitations of particular combinations of bearing and journal materials, lubricants and lubrication methods. Engineers in general should not be criticized for this lack of information regarding plain bearings. A very extensive acquaintance with conditions in an equally extensive number of installations is necessary in order to make logical and accurate deductions as to the fundamental principles involved. For this reason the assembling and logical compilation of such information will be essentially dependent upon the manufacturers of bearings and of bearing materials.

All engineers have, however, observed the wide variance in results obtained from bearing metals of the same chemical properties. To illustrate, an engineer may have run half a dozen tests on a "gun metal" bearing, (a bronze analyzing approximately 88 per cent. copper, 10 per cent tin, 2 per cent. zinc) and have obtained as many different results as he ran tests, while the conditions of the test were apparently identical. This condition of fact without an understanding of foundry practice as well as of basic principles is difficult of understanding.

Matter of Lubrication

At the Standards Committee session of the Society of Automotive Engineers there were several speakers on the subject of lubrication. During the discussion much stress was laid on the fact that only when the shaft is revolving at high speed is there a perfect film of lubricant or a film even approximating perfection. At all other times there is metal to metal contact of varying degrees. It was unanimously conceded that were the film of lubricant constant and sufficient, wear would be a negligible factor. It might be mentioned in passing that the supply of lubricant is rarely sufficient to secure this ideal condition during operation. Moreover, this ideal is never approached when starting up or shutting down. Metal to metal contact—more or less complete—is an unfailing incident in the life of every bearing. It may be continuous or it may be intermittent but it is unavoidable and is always accompanied by wear.

It becomes quite essential that we consider first what constitutes wear, and second, what material will offer the greatest resistance to wear. By careful examination we find that all bearing surfaces, shafts and bearings alike, are actually rough, and that when metal to metal contact is permitted these rough surfaces interlock. The result is that as soon as the shaft or other member moves, the molecular structure of the softer metal is torn away. This fact being established we are induced to determine what bearing metal will best resist this pull of friction.

Engineers and laymen alike are accustomed to think of a bearing metal as a homogeneous alloy analogous to a chemical compound. However, a combination of practical foundry experience and of the essential theory of metallurgy leads to a realization that a bearing metal is not essentially a chemical compound but is a mechanical mixture of chemical compounds, solid solutions, and segregated metals and gases. These gases are introduced at the time of the alloying the metal. Theoretically the occluded gases are expelled incident to the slowing down of the molecular motion during the cooling of the metal. However, it is found upon microscopic examination that such is not always the case as frequently the gases remain in the mass causing porosity. This condition is obviously fatal to homogeneity.

From a consideration of the facts previously presented we are led to believe that a desirable bearing metal is one which is dense and homogeneous, incidentally density is reflected in the hardness of the metal Since copper and tin do not possess a perfect affinity for each other, and copper and lead absolutely no affinity, the difficulty of obtaining a homogeneous alloy is apparent. This, however, can be controlled to a great extent by experience and care in foundry practice. Lead, however, is always inimical to homogeneity and hence bearing metals containing lead will offer a lessened resistance to wear and a shortened life. They will, however, adjust themselves to conditions (i.e. "wear-in") to a considerable degree and are not prone to injure a journal in the event of failure of lubricant

The degree of comparative hardness necessary will depend on the conditions imposed by the installation, possible failure of lubricant, frequency of lubrication, length of service desired, accuracy demanded of the unit, (or conversely, the permissible looseness or play) both initially and during the life of the installation, and cost, the softer bearing metals being usually cheaper than the harder metals.

After determining the desired qualities, the problem arises as to the manner in which these qualities are to be attained. Is it sufficient to specify the chemical composition? It is, perhaps, generally realized that castings of a given size poured at different temperatures from the same alloy will possess different physical characteristics but it is not perhaps as generally realized that castings of different sizes poured at the same temperature from a given alloy will also possess different physical characteristics. Occluded gases can be expelled only by the proper method of gating molds and since this condition varies with different alloys, it is essential that the foundry producing a dense metal must be experienced and expert in the particular alloy they are creating.

The Rod Mills at the Sydney Steel plant, Sydney, N. S., will re-open the first part of next week, and the Wire Mill will start about the same time, according to the general manager of the Dominion Steel Corporation.

News From the Welding Field

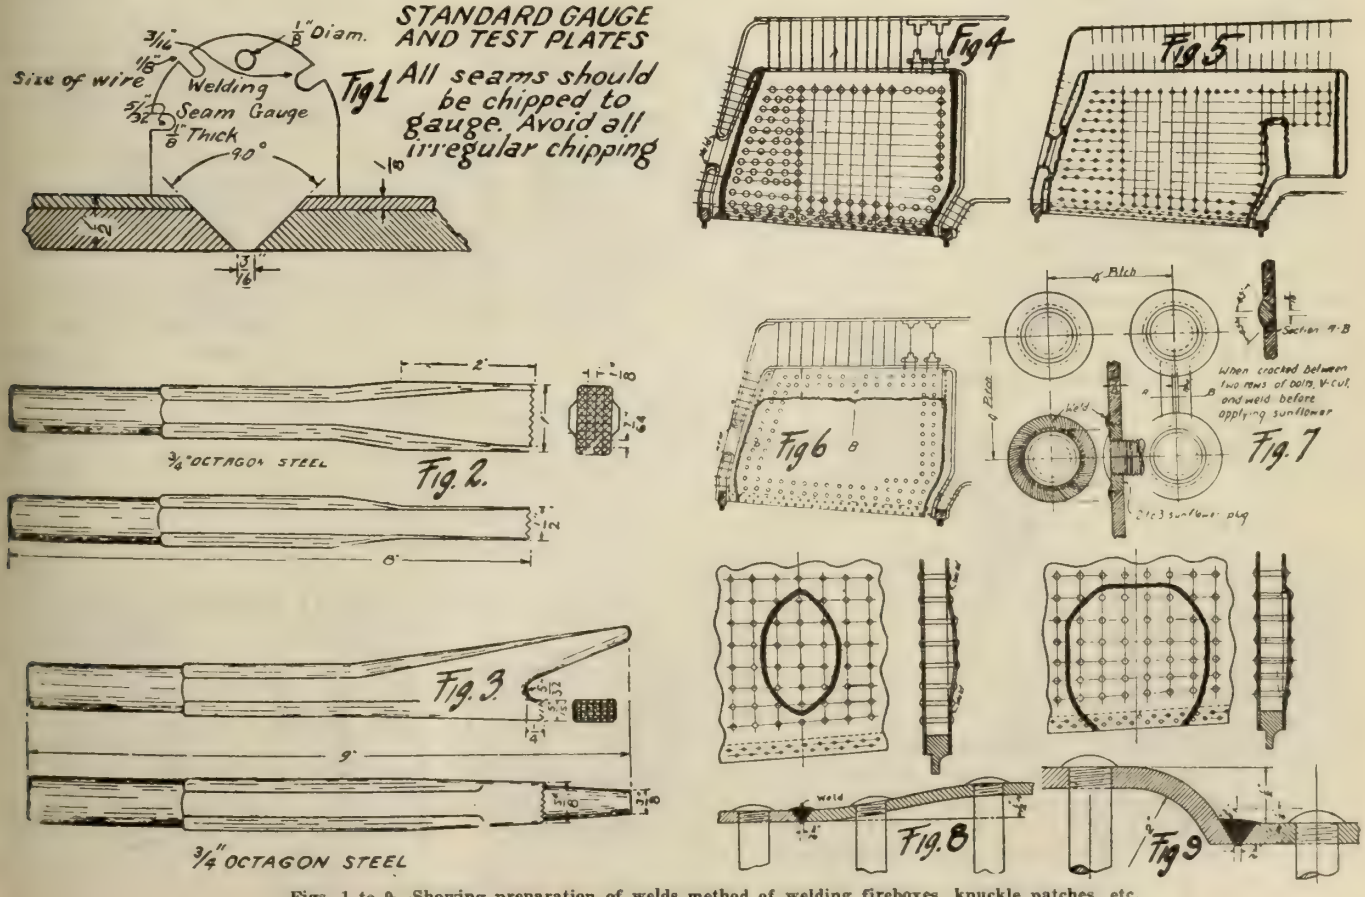
Best Methods of Welding Locomotive Boilers

Welding Electrodes Should Have Even Flowing Qualities—Proper Preparation Means Good Welding—Repairing Front Portion of Crown Sheet—Mistakes Which Should Be Avoided

THE RESPONSIBILITIES of good welding depend largely upon the skill and experience of the operator. Welding electrodes that have the approved chemical constants or elements which will give the best tensile strength which conditions may require should be adopted for boiler repairs. Another important point is that welding electrodes which are to be used on firebox welding should have even-flowing qualities; that is, the globules of metal should flow from the point of the electrodes to the work in a steady stream, so they will not interfere with the skill of the operator or the functions of the electric arc.

The efficiency of the operator should be fully determined before he is allowed to perform any welding in locomotive fireboxes by having him weld specimens at least once each month. The welded specimens should be forwarded to the engineer of tests who will test them for tensile strength. The efficiency of the welded specimen should be at least 75 per cent. of the firebox steel used, before the operator is allowed to do any firebox welding. It is important that good judgment should be exercised in assigning operators to autogenous welding in fireboxes.

Importance of Preparation



Another important feature is that no piece of work should be welded unless it is properly prepared. That is, all seams should be beveled as shown in Fig. 1, and should be thoroughly cleaned, free from grease, scale and other foreign substances. It is very essential that the weld be made on bright, clean metal and that this condition be preserved throughout the entire welding operation. The use of a roughing tool as shown in Figs. 2 and 3, or a sand-blast machine, may be used for cleaning purposes. All seams should be carefully fitted and beveled to 45 degrees, not allowing more than ¼ inch, or less than 3/16 inch space at the bottom of the "V" as shown in Fig. 1, as determined by the use of a gauge.

If the opening at the bottom of the "V" closes to less than 3/16 inch, the welder should stop and have it chipped to the standard opening. Under no condition should the plate be burned with the cutting torch to enlarge the opening, unless it is going to be chipped afterward.

Welding of Complete Fireboxes

All sheets should be beveled on the rivet line from the fire side, see Fig. 4 and plates should be fitted into the mud ring, held together with strong backs or clamps about every 12 inches in order to hold the plates in perfect line. The sheet should then be tack-welded between each of the clamps, the tacks being from two to three inches wide. After this operation has been

The suggestions contained in this article will be presented in the form of a report before the Master Boiler Makers' Association Convention at Chicago in May, 1922. The report committee responsible for these findings consisted of H. H. Service, supervisor of welding, Atchison, Topeka & Santa Fe Railway, Topeka, Kansas, chairman: I. J. Pool, and R. W. Clark.

Figs. 1 to 9—Showing preparation of welds method of welding fireboxes, knuckle patches, etc.

performed, the clamps should be re-welded. Do not remove the firebox from the ring until after the welding has been completed. All seams should be reinforced 20 per cent. of the thickness of the firebox sheet on the fire side, and when it is possible to do so, seams should be reinforced on the water side approximately 10 per cent, especially on the crown sheet.

All welding should be started on the bottom of each intermediate space and finished at the top of the seam. For all firebox work, current values from 100 to 125 amperes will give the best results when properly handled by the operator using a 5/32 inch diameter electrode. The cost of welding firebox seams per lineal foot is 90 cents for labor, material and current.

The sheet should be bolted to the mud ring after it has been properly beveled and fitted in place. Staybolts may be applied except the rows adjacent to the seam which is to be welded. All horizontal seams should be held in place with strut bolts and tack-welded every 12 or 14 inches. Then weld intermediate spaces alternating from the centre space to the spaces at either end. Vertical seams should be tack-welded similar to horizontal seams. After being tacked, start welding at the bottom space and finish at the top space. Current values for successful welding on this operation are the same as for firebox welding described in Fig. 4 and Fig. 5.

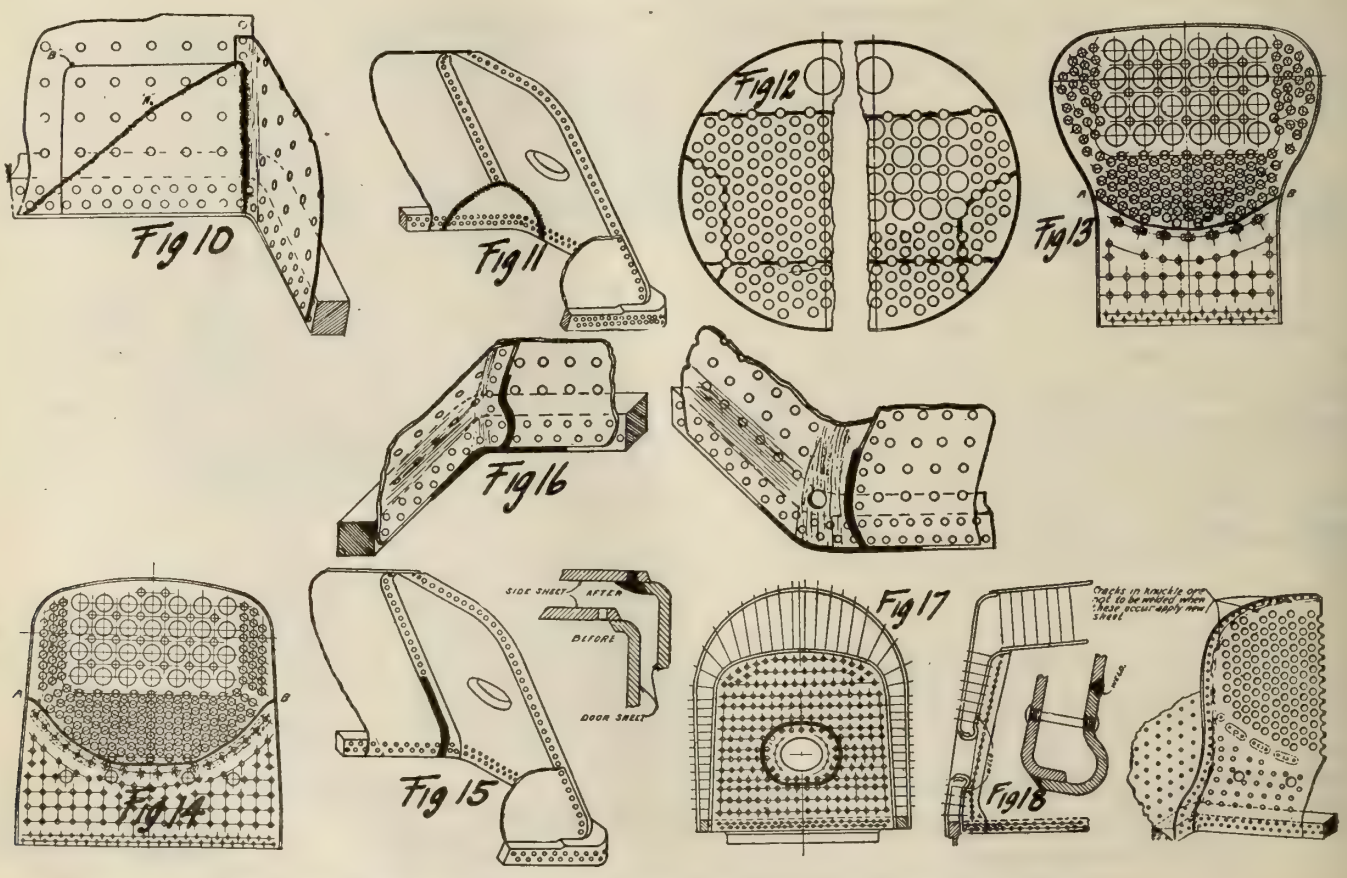
Firebox Sheet Knuckle Patch

Preparation for the firebox knuckle patch Fig 6 may be followed as outlined for the welding of half side sheets or door sheets. The use of strut bolts can be applied to hold the patch in line when necessary, while it is being tack-welded. All strut bolts should be removed after the patch is welded into position. Under no circumstances should the knuckle patch be less than 12 inches from the crown sheet.

Weld the horizontal seam first, then tack-weld the flanged sheet to the wrapper sheet. Remove all strut bolts and weld intermediate spaces, working from the bottom on either side of the patch upward, finishing at the top. The method indicated in Fig. 7 is to be used to repair cracks at staybolt holes in firebox sheets, where not more than 6 sunflowers are necessary to complete repairs, and not more than 4 sunflowers will be joined together. This system may be used in main shop general repairs, sunflowers not to exceed 3 inches in diameter.

Repairing Small Portions of Side Sheet

When the defective portion does not extend over six staybolts, repairs can be made as per instructions given for Fig. 7 which give very efficient results. When the defective portion is larger it is then advisable to use methods as shown in Fig. 8 by removing the defective portion and applying a patch of an elliptical or circular shape. In preparing the patch, sufficient metal should be allowed so that when the patch is dished ⅜ to ½ inch in the centre, the opening at the seam should not be more than ¼ inch wide at the bottom of the "V", and not less than 3/16 inch.



The patch should be held in place by strut bolts and tack-welded on the right or left side; then weld this seam of the patch before the opposite side is tack-welded, so as to allow the patch to draw in one direction. After this has been completed, allow it to cool before starting on the opposite side. By so doing there will be only one contraction of the patch. All welding should be performed from the bottom upward. Should the defective portion of the side sheet extend down to the mud ring rivets, apply the patch as in Fig. 9, the welding operation being the same as outlined for Fig. 8. Should the defective portion be at location as shown in Fig. 10, the seam may be applied as indicated by line "A".

Should the plate at the corner of a firebox become defective and it is necessary to remove a portion of the side sheet and the door sheet, it is advisable to apply a patch to both sheets as in Fig. 11 Should it be necessary to make repairs according to Figs. 12, 13 and 14, the work should be done by welding from the fire side of the sheets and reinforcing them on the water side.

Welding of Seams

Should the seams become defective and cause considerable trouble, repairs can be made with the electric arc process as shown in Figs. 15 and 16. Remove the defective portion of the flange, which is giving trouble, by cutting through the back of the rivet holes, bevel the sheet 45 degrees and tack-weld it every 12 inches; then weld the intermediate spaces. The weld should not be any thicker than the flange of the

Methods of Securing and Manufacturing Rubber

Wild and Plantation Products—Bringing the Latex Into Marketable Form—Methods of Collecting Differ According to Locality—Manufacturing Process—Extending Hose Pipe—Reclaiming

By JAMES FEA

HAVE YOU ever paused to contemplate how much your daily round brings you in contact with the substance rubber? You get up in the early dreariness of a rainy morning, turn on by means of a rubber-handled switch a flood of electricity through rubber-insulated wires, proceed to a rubber-tiled bathroom, shave yourself with a rubber handled razor, wash yourself with a rubber sponge, return to your room and don, amongst other things, rubber garters, rubber belt, rubber soled and healed shoes and perchance a rubber collar.

After breakfast you protect yourself against the elements with rubber overshoes and rubberized coat, and just as you leave the house you make sure that the rubber tobacco pouch is in your pocket, that your hard-rubber fountain pen is safe in its place, and that you are in possesion of your rubber-stemmed pipe and cigarette holder. You then proceed to the corner and catch the bus with its huge rubber tires, not to mention the many pounds of rubber in that complicated machine in the form of gaskets, washers, insulation, etc. Have you ever wondered where it all came from or how, or have you just taken it for granted as you would the stone in the rasin-pie or the fly in the currant-bun?

The Discovery of Rubber

The earliest mention of rubber was in 1493 when Columbus, during one of his rambles abroad, saw the natives of the island of Haiti playing with balls which were made from the gum of a tree. However it was the Portuguese who late in the sixteenth century, found that the Hevea tree which grew in Brazil, produced a gum which could be used very successfully in waterproofing their garments. From that time the industry went ahead and was taken up by other countries. About 1910, the introduction of cultivated or plantation rubber was signalized by a boom which netted much for some and was extremely disastrous for many others, after the fashion of booms. Since then, the rubber factories have grown and multiplied, and to-day we include the substance among our daily necessities.

What the future may bring, is a subject for conjecture and also a source of worry to rubber producers, for at present more rubber is beig grown than can be utilized, so further uses will have to be found. Experiments in the use of rubber in paving streets and in making furniture have not been unsuccessful and who can tell but that the little demon who chortles over broken dishes may be disconcerted by the substitution of rubber cups and saucers.

Two Types of Rubber

There are two types of rubber on the market, the wild, and the plantation or domesticated. The former comes from Brazil, Peru, and Bolivia on the banks of the Amazon, as well as from Central America and Mexico. In the Old World it is found in Africa, Northern India, and the East Indies.

The Para rubber from the Amazonian forests is perhaps the best known to the uninitiated. It comes in three grades, fine, medium, and coarse or negro-heads, the quality depending on the skill with which it was first treated in the raw state. The rubber gatherers live in small settlements called estradas, on the rivers' banks. Through the dense tropical growth they clear paths starting and finishing at their camp, and during his daily trip along this path, the native passes some hundred Hevea trees which are about eighty feet in height and as much as four feet in diameter. At a convenient distance from the ground, he makes a cut around the trunk and at intervals hangs small tin cans to catch the thickish, milk-like fluid, which oozes from the cuts in the bark. As the tins are filled, they are emptied into a larger vessel for treatment at the estrada.

In order to bring the latex, as the fluid is called, into a form which can be marketed, the worker builds a fire of palm-nuts which gives forth a very thick and pungent smoke. Into the pan of newly collected latex a wooden paddle is dipped, and the paddle with the adhering rubber is held over the smoke until the rubber solidifies. The paddle is again dipped into the latex and the next coat similarily treated over the fire. In time the worker has made a large ball which is cut in two in order to remove it from the paddle. You have no doubt, seen these in rubber exhibits, and their smoky, hammy odor still permeates your nostrils. This is the first quality, the other two differing in that they are made from the scrap and refuse from the fine Para. It is not an unusual thing to find in the coarse Para, such unrubberlike articles as old boots, charred bones of some lately lamented animal, and numerous pieces of bark and palm-nut shells.

Another Method

In Bolivia and Peru, the rubber is derived from another species of tree, and is distinguished by the name of Caucho. Here they fell the trees and collect the milk from numerous cuts that are made in the bark, and coagulate it by means of soap, lime, or potash, the lumps being removed and later pressed into square blocks known as "Peruvian slabs."

In Central America, can be seen small, semi-clad figures shinning up to collect caucho-milk from trees which are often well over a hundred feet in height. The procedure here is to make "V" shaped cuts in the bark and collect the gum in calabashes. When he has taken the milk from several trees, he pours it into a shallow tin and adds the juice of a vine growing in those parts. This has the same effect as smoking or the adding of an alkali, and coagulates the rubber into curds which float on the top, and are skimmed off and kneaded into cakes to remove the surplus water.

In Mexico, the story is different, for in place of huge trees, scrawny bushes are the source. These Guayule bushes are cut down and crushed in pebble mills. The rubber contained in the cells of the plant is removed by flotation, the rubber rising to the surface of the water and the residual matter sinking. Guayule rubber is of sufficiently high quality to permit of its being used in the manufacture of surgical goods.

For many years the grade of rubber from Africa did not measure up to the standard set by the New World fields due to the careless manner in which the latex was coagulated and packed; however the introduction of better methods by European experts is gradually improving conditions. Congo-Kassai is one of the better known African rubbers and can be recognized by its dryness and woody smell. From Malay and the Far East comes a substance by the name of gutta-percha, a second cousin to rubber, but while the mode of treatment and collecting is the same, is has slightly different characteristics, being inelastic and inclined towards brittleness when cold. It is used considerably in the manufacture of golf balls and in insulating cables. Another kindred substance to rubber is balata, a gum taken from a tree which flourishes in the forests of British Guiana. Its principal use is in the manufacture of machinery belting.

Cultivated Rubber

The rubbers mentioned in the foregoing paragraphs have all been of the wild variety, but there is another kind which has put the industry upon an entirely different footing, namely the plantation or cultivated rubber. The domestication of the Hevea is almost entirely due to the efforts of a Mr. H. A. Wickham, who had experimented with the cultivation of this species in the Brazilian districts, and came to the conclusion that the same could be grown successfully in the East. The problem narrowed down to the transporting of the seeds, for the Brazilian authorities

were very jealous of their monopoly and hampered any movement that might jeopardize it.

Mr. Wickham took advantage of the misfortunes of a Scotch sea captain whose ship was stranded in a Brazilian port without any cargo for the homeward trip. He chartered the boat and after considerable trouble, loaded it with crates containing the seeds of the Hevea tree at an unfrequented spot up the coast. It was necessary that clearance papers be obtained at Para before the vessel could start on its journey, and it was here that he expected to meet all sorts of objection if not prohibition. Through the good services however, of the consul there, permission was granted for him to convey certain "rare and delicate botanical specimens for Her Brittanic Majesty's Kew Gardens in England," the nature of these specimens being unknown to the authorities for they did not take the trouble to investigate the unusual cargo.

Eventually the seeds reached Kew Gardens and in June of 1876, over seven thousand young Hevea plants were flourishing there, tier upon tier. As these became more hardy they were distributed among experimental stations in Ceylon, Burma, Java, and Singapore and for several years plantation rubber was taken up more as a hobby, but the boom in 1910 saw hundreds of companies formed for its cultivation, and plantation rubber was here to stay, and through its advancement the rubber industry as a whole has prospered.

The treatment of plantation rubber varies slightly from that of the wild. The milk is put in shallow pans and after reducing to a uniform rubber percentage, dilute acetic acid is added, curdling the solution. The curds of rubber are taken and the moisture removed before running through fluted rolls which work it up into long sheets, with markings corresponding to those on the rolls. These are usually diamond shaped and provide ventilation when the rubber is packed. As it comes from the rolls it is white in color but gradually it assumes a yellowish hue upon aging and a further smoking treatment over burning cocoa-nut shells gives it a brown color.

Process of Manufacture

So far only the planter's share of the treatment has been discussed. After unrecorded experiences with native uprisings, longshoremen and railway strikes, not to mention the rubber broker's kindly interest, it finds its way into the tender hands of the rubber goods manufacturer, who by the way is passing through an interesting period of transition from the regime of inherited rubber folk-lore to that of scientifically trained experts; or in other words, from the flannel-shirted boss to the white collared manager.

As he receives the crude rubber, it is packed in wooden boxes and barrels of various shapes and sizes. The first step is to remove the accumulated dirt and occasional scorpion, and to put it in such a form that it can be easily handled in the succeeding steps. The washing machine consists of two steel rolls about forty-eight inches long and twenty inches in diameter with surfaces marked by diagonal grooves. The rubber, which is cut into suitably sized pieces, is fed in between these rolls, water flowing all the while over the point where the rolls are closest together. The chunks of rubber are rolled into long strips while the splinters of wood and other foreign matter are washed away. Before the rubber can be handled again it is necessary to dry it. This is done by either of two methods; hanging the sheets of rubber in a kiln-like room, or placing in a steam heated oven under a slight vacuum.

The rubber is now ready to be mixed with the ingredients as demanded by its ultimate use. This is carried on in the heart of the factory—the mill room, an exceedingly dusty though interesting spot. Contrary to general opinion, the rubber as seen in most of the articles of everyday use, has only a very limited percentage of rubber, the balance being made up of such compounds as zinc oxide, white lead, magnesia, flour, graphite, oils, greases, sulphur, etc. In addition to these there are also used such powders as carbon black, ultramarine blue, chrome green, antimony red, barium white, etc., depending on what color is desired in the final product. The proportioning of these ingredients is not an exact science, or at any rate is not considered as such in many plants, for their methods are more or less of the trial and error variety; however the day is not far off when the compounder will simply work out his "receipts" on a slide rule or from a book of tables.

After the batch, as the collection of rubber, powders and oils, etc. is called, has been weighed out by the compounder, it is turned over to the mixer on the mill. There are usually quite a number of these machines run off one drive shaft. They consist of two smooth steel roll up to eighty inches in length and about twenty inches in diameter, and in order to produce a grinding effect on the rubber, the two rolls are run at slightly different speeds.

The rubber is soon worked up into a plastic mass like chewing gum, the process generating a large amount of heat and necessitating the cooling of the rolls by means of water circulating through them. As the rubber becomes "warmed up," the other ingredients are slowly added and assimilated by the gum, sulphur, the vulcanizing agent, being the last to enter the mass. When the proper degree of mastication has been reached, the mass is cut off from the mill in the form of slabs about two feet square and about half an inch in thickness. These are painted with a solution of chalk and water to prevent the pieces from sticking together when piled away for future use.

When the rubber is to be used in the manufacture of tires, belting, etc., the calender is the next machine employed. It consists of three large steel rolls superimposed, one on top of the other, of abut twenty inches in diameter and up to six feet in length. The rolls can be either heated by steam or cooled with water, and the successful operation of the calender largely depends upon the adjusting of the temperature of each roll. The machine is capable of rolling the rubber into sheets of varying thickness, and in forcing the rubber by friction, into the pores of the ducks or other fabrics required in the process. The distance between the rolls can be exceedingly finely adjusted, and the altering of the thickness of the rubber by some one or two thousandths of an inch can be done by the most clumsy workman.

Frictioning the Fabric

When the operator desires to friction the fabric—that is, to force the rubber into the pores—he causes the central roll to revolve at a different speed to the other two rolls, the rubbing action doing the trick. When he wishes to sheet the rubber to a certain thickness all three rolls turn at the same speed and their effect is the same as that of the rolling mill in a steel plant, or even the homely clothes wringer. By placing knives against the roll, the rubber can be cut to any desired width as it is being calendered.

A few words concerning the making of belts, hose, and press goods would not be amiss. There is nothing very mysterious about the making of a rubber transmission or conveyor belt, consisting as it does of layers of rubberized duck so folded and built up that the sems will not spring apart when the belt is put to any strain. Most of the smaller belts are made up automatically by machines which cause the fabric to be folded over to the required width and then pressed firmly by a small pair of rolls. If an endless belt is desired the two ends are joined together after separating the plies and making them interlap, the joint being strengthened by stitching. The curing or vulcanizing is sometimes done in a large iron cylinder, in which the roll of belting is in an atmosphere of steam at about thirty or forty pounds pressure—that is about 250 degrees Fahrenheit. Another method is to place the belt in a large press and subject it to a combination of heat and pressure. The conveyor or belt differs from the other in that it has an additional face of rubber to add to its wearing properties.

Making Hose

There are several methods of making hose but the most common and simplest is to build up on iron poles or tubes of the diameter of the bore of hose desired several layers of rubberized fabric on an inner tube of rubber. When the required thickness of wall is reached, the hose is spirally wrapped with wet cloth and the lengths cured in steam heated cylinders. To remove the vulcanized

hose from the metal mandrels, compressed air is introduced between the inner tube of the hose and the mandrel, making the stripping off of the hose a comparatively simple matter. As this method limits the length of each piece to about fifty feet or less, another process is resorted to for longer pieces.

A machine known as an extruder, which forces the rubber through a die forming it into a seamless tube, is used here, the tubes being later covered by a fabric wall in a modified knitting machine. Several alternating layers of rubber and fabric are built up before vulcanizing. The vulcanizing is done in a press which gives the corrugated or smooth finish, as desired, the hose all the while being inflated with air to keep the walls from caving in until the curing gives them the ultimate rigidity.

The ingenuity of the compounder is taxed to the limit by the innumerable uses to which hose is put. One which meets the needs of the gardener is absolutely useless to the man at the gasoline station as gasoline is an active solvent of rubber unless the rubber is especially fortified against it. Or again; a rubber hose that is used to convey compressed air would fall to pieces in a couple of weeks if it were compressed to carry steam as the latter will rapidly rot ordinary rubber. The pressure which is exerted on the walls has also to be taken into consideration, and such devices as placing iron or steel wire between the layers is called into service.

Recent Innovation

A fairly recent innovation in making of long lengths of hose, makes use of a lead-pipe making machine. The rubber and woven fabric hose is fed into this powerful press which coats it with a lead pipe formed in such a way as to give any desired surface to the hose. This is taken up on large drums, and after applying internal pressure to force the hose against the lead covering, the reels are put in vulcanizers and cured. When this has been accomplished, an ingenious combination of knives and rolls remove the lead covering. A length of hose up to in the neighborhood of fifteen hundred feet can be made by this process.

There is another place in the average rubber factory which is usually of great interest to the visitor—the press goods section. Here the never-ending variety of gaskets, bumpers, heels, etc., are made. Their story in a nut-shell is this; the uncured rubber is placed in sturdy steel or iron molds which shape the article with the aid of heat and pressure. Water supplies the pressure through hydraulic rams, and steam the heat. The combination of these two forces causes the rubber to at first flow, and then solidify in the form given by the cavity in the mold. If it is undercured, it will not be elastic and resilient, and if over-vulcanized, it will be hard and will break easily. A high percentage of sulphur and a long period of vulcanization will produce a hard rubber which is capable of receiving a very respectable polish.

Vulcanization

The question of vulcanization is an interesting one, and one in which there is still room for research. It was in 1893 that an American, Charles Goodyear by name, was successful in finding a method of making rubber more durable. He called this process vulcanization, and made use of sulphur to bring about the phenomena along with heat and pressure. The length of time required to cure a rubber tire is a considerable factor in governing the cost, so as sulphur alone is not a very fast agent, accelerators, as they are called, are brought into play.

The composition of these vary and as a rule are surrounded by a high wall of mystery in the factory, but their presence in the rubber cuts down the time in curing very much. To give some idea of their power, try and pronounce the name of one of them—Hexamethyllenetetramine. Vulcanization can also be effected by exposing the objects in some sulphurous atmosphere such as carbon bisulphide. This method is utilized in the manufacture of rubber gloves and their like. A porcelain form shaped like the hand is dipped into a solution of rubber and some solvent like benzol—in other words, a rubber cement. A certain amount adheres to the form which is then placed in the fumes of the vulcanizing agent for the required period, and then stripped off and dusted with soapstone, when it is ready for the market.

There is another department in the rubber factory which deserves mention, namely the reclaim. Here it is that all the scrap is sorted out and put into circulation again. The scrap can be roughly divided into three groups, unvulcanized, and rubberized fabric. The treatment of the first is simple as it is only warmed up on the mill and used over again. The cured scrap is reduced to a feathery-like powder and then mixed with fresh batches of rubber as a filler. The coated ducks and fabrics are ground between rolls with corrugated faces, and come out in the form of a fluffy appearing substance. This is mixed with fresh batches and used in the cheaper grade of goods, or in those which require a certain amount of strength which is imparted by the numerous fibers of duck. It is pretty good betting that the pair of rubber soles on your feet at the present moment were once a part of a flivver or Rolls-Royce in the shape of tires.

In closing, it is only fair to mention the artificial, or synthetic product. Many a budding chemist, as well as those in full bloom, have discovered how to make rubber in a test tube out of anything but the rubber plant, but although they deserve much honor for their work, and although some day we may be loudly claiming our home town as their birth-place, they are at present wasting their time, for there is about as much sense in producing a synthetic rubber, as there is in making an artificial dande ion for the front lawn—nature puts too many there already.

NOVEL BOX SPANNER

Many improvements continue to be made on engine ring accessories which have been familiar since engineering was born. The box spanner, for example, is one of those simple tools which one is inclined to take for granted, but even it can be made better for many purposes by the exercise of a little ingenuity. A British firm has brought in a new type which can be used conveniently in a great variety of awkward positions. The box head is connected with the shank by a universal joint which allows the shank to be tilted so as to clear the projections which might interfere with the use of the spanner.

CUTTING STEEL BY FRICTION

In the cutting of steel it is usual to employ either a tool of the saw type or a cutting flame supplied by oxy-acetylene or the electric arc. Some time ago, however, it was found that a plain disc driven at high speed would cut through steel simply by the heat of friction. This device has been considerably developed by a number of British machine tool makers in association with each other. The saw consists of a plain mild steel disc with a notched edge. In recent tests one user cut eight large joists right through in 40 minutes. In another case the saw was successfully used in cutting manganese steel rails, which, previously could not be cut except by the oxy-acetylene flame. A manganese tramway rail can be cut through in 72 seconds. An ordinary tramrail can be severed in 37 seconds.. Owing to its efficiency and simplicity it is felt by those interested that the friction saw, as it is called, will come into extensive use for cutting all kinds of steel sections.

ROLLER CAGE SWAGING MACHINE

The Langelier Mfg. Co., Arlington, Cranston, R. I., have recently brought out their No. 3½ A T 4 roller cage type swaging machine. The design is somewhat unique, and the new machine has a hardened steel ring driven into the head, which receives the revolving cage carrying the rolls. Other features of the mechanism follow the general lines of machines previously produced. It is claimed, that this new tool is especially adapted to solid work in both swaging and sizing operations. Various adjustments including that to the speed of the rolls enables a fairly large range of work to be handled.

Practical Ideas from Practical Men

CHUCK WRENCH HOLDER

By Harry Moore

Special lathe chucks which are tightened by means of a central screw, can be operated much quicker, if a holder as shown is used in conjunction with the regular type of wrench for ordinary chucks. The holder is made to fit the tailstock, and it is bored at front to take the body of the wrench, at the same time being slotted to clear the handle.

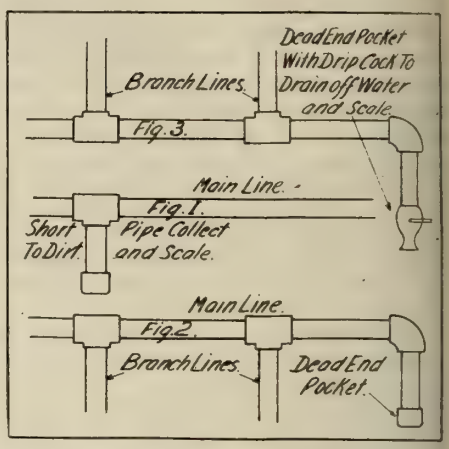
The screw used, must of course, have a head to fit the square of wrench. In operation the tailstock spindle is advanced to a convenient distance from the work and locked, leaving enough space between the end of wrench and the chuck face to allow the screw to be withdrawn. The wrench is used in the same manner as an ordinary one, the advantage being that it is always in place ready for use, whereas a loose wrench of any kind has a distinct tendency to slide through to the floor, or to be absent mindedly placed in different positions around the lathe, resulting in useless motions and lost time.

HEAVY DUTY TOOLPOST COLLAR

By Harry Moore

In turning some odd shaped forgings, trouble was experienced with the tools under repeated heavy knocks as the work rotated. The result of this was a gradual taper as the tool progressed which necessitated another cut to rectify before the finishing cut was taken.

The sketch shows a collar and shoe made to overcome this objection. The collar, A, has a slot cut across the centre into which the shoe, B, sits. A tapped hole in the end of B admits a headless screw, the end of which enters a recess or dimple in the bottom of slot. The piece B is raised or lowered by the screw to approximate height of centre of tool, and being raised to a taper, the tool is finally adjusted by moving it in or out a little. This idea is not advanced as an improvement on the regular collar and rocker for general work, but as a better method for the type of work stated above.



SAVING THE AIR TOOLS

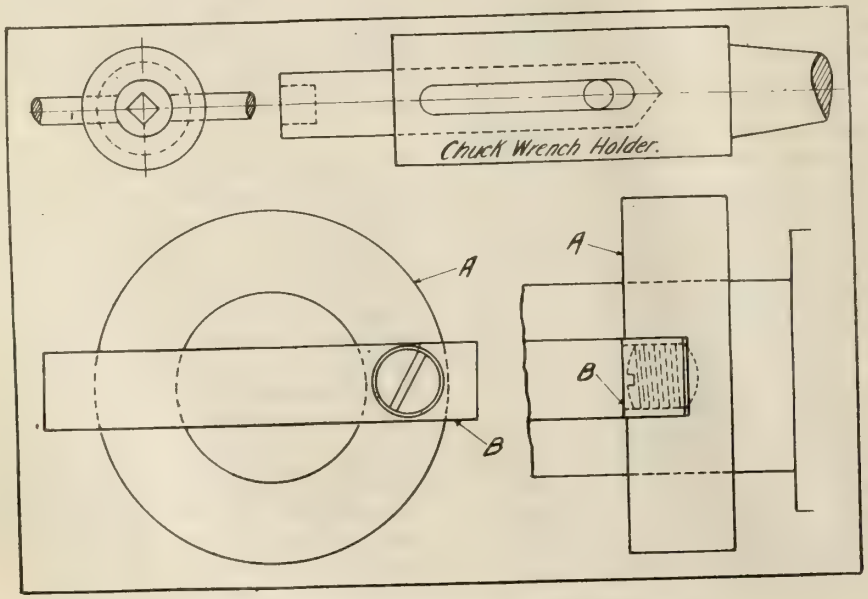
By C. Rye

From personal experience as repair man on air-driven tools such as drills, clippers, riveters, etc., I have found, that according to the condition some tools come back for repairs, some advice regarding their care is badly needed. The working parts of such tools, especially the valves, are fitted to very close limits, and naturally all dirt should be kept away from these parts, otherwise trouble is sure to follow. As most of our repair work was caused by scale and dirt from the air pipe line, I devised the scheme shown in sketch to prevent the necessity of further repairs from this source at least.

In the old air line I placed short pieces of pipe as shown, these collecting any scale or dirt that might be rolling along the bottom of the pocket. I continued the dead end of the line a little beyond the last branch of the air line. In this pocket would collect all dirt and scale.

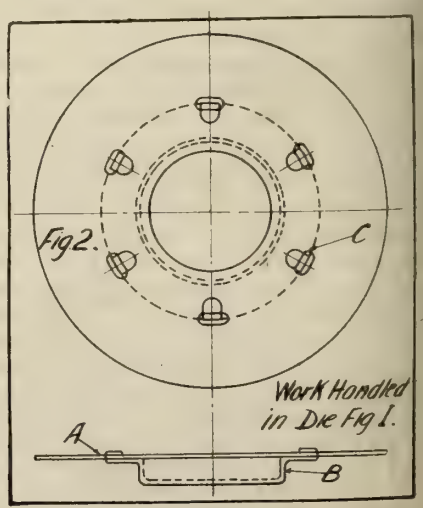
When piping new lines I took all branch lines off main at the top and

Showing how author caught dirt in the air pipes.



put in a dead end pocket, this allowing dirt that might have been knocked loose, or even rust from getting in the branch lines, later finding its way to the valves and cylinders.

Many air tools have strainers in them when new, but quite often these are lost when they are being overhauled. I also found that piping in this way gave us dryer air. This system also applies to rock drills, coal drills, etc., and to my mind ought to work well on steam-driven tools as well as air.

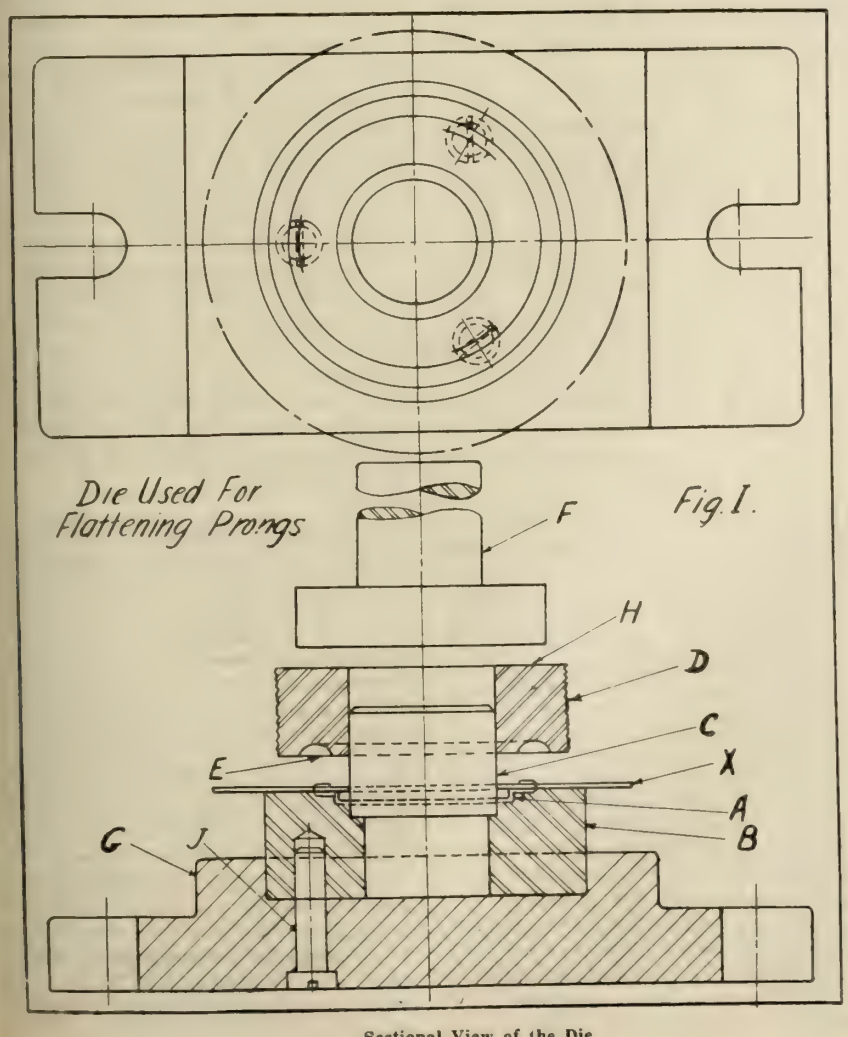


PUNCH AND DIE FOR FLATTENING PRONGS

By Scriber

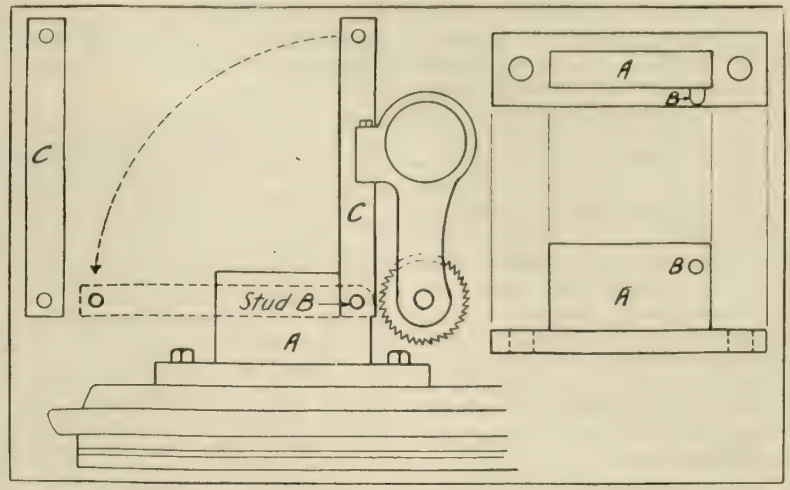
A simple die designed for turning down six prongs used in attaching two metal parts together, is illustrated in Fig. 1. The principles employed in the operation of the die will be best understood by first noting the construction of the parts shown in Fig. 2. This shows a plain disc "A" having six slots cut in it; a saucer shaped piece "B" having

Showing the wrench holder and heavy duty tool post.



Detail of the work handled in die on Page 29.

six prongs "C" formed thereon which pass through these six slots, is also shown. The purpose of the die shown in Fig. 1 is to turn these six prongs down from an upright position after they are passed through the slots and to flatten them as shown.



Referring to Fig. 1 the small diameter of the saucer shaped piece enters the recess "A" in the formed block "B," the large disc is here indicated as "X" and this is placed over the prongs, both parts being located central by means of a stud "C" passing through the hole therein. Over this stud "C" is placed a ring "D" which has a formed groove "E" cut in its lower surface. The flanged piece "F" is held in the ram of a foot press while the die shoe "C" is attached to the bolster plate of the press. When "F" is pushed down the recess "E" in "D" is caused to engage with the upright prongs and turn them down to approximately the shape of the recess "E."

The ring "D" is then removed from stud "C" and is reversed bringing the flat surface "H" on the ring nearest to the work. The foot press is then operated again and "F" forces down ring "D" until the flat surface causes the prongs to lay flat in the position shown. The ring "B" is held to "G" by screws "J" while the periphery of "D" is knurled to form a convenient finger grip for removing this by hand off the stud "C."

Sectional View of the Die.

This makes a cheap and efficient tool, that when set up requires practically no attention from the operator except to remove and put in the work, followed by reversing the ring "D" to perform the two functions for turning over the six prongs and flattening the same.

Illustrating how the author made the corner of radius shape.

MILLING RADIUS QUICKLY

(By V. W. J. Coffin)

The stretch shows an economical method of rounding the ends of flat bar stock. Previously this job had been accomplished by grinding, but proved a slow and tedious task. This work is 15in. long and it is drilled as shown, the radius starting from the centre of the 7/16in. hole at the end. We decided to speed up the operation by milling, so a tee shaped casting, A, which we had on hand was utilized. It was filled at one end and side with the stud, B, which was relieved in such a manner as to allow the stock to be placed and clamped. A hand milling machine was used, and the table raised so that the stud, B, was in a line with the centre of the arbor. A 2½in. stock cutter was used.

The piece was placed on stud B in a perpendicular position, and table was advanced up to cutter. The table clamp was then tightened, and all that was necessary was to pull down on the stock a quarter turn, the cutter forming the radius. We merely reversed the part to form radius on the other end.

VALVELESS GEARLESS ENGINE

The idea of an engine without valves or gear has been realized in Great Britain by the construction of an engine, which in the works at least, has been given remarkably promising results. This engine has three cylinders; and except for the ports it has no valves. There is not a single gear wheel and all the usual cams, shafts, tappets and springs and even the timing gear are cut out. The only moving parts are the crank shafts, pistons and connecting rods. The experimental engine was rated at ten horse power and on test developed twice as much. The cycle of operations is not easily described without a detailed diagram, but it can be said to depend upon ingenious inter-working between the three cylinders. This engine has been specially designed to meet the conditions in overseas countries where an extremely simple engine not requiring difficult repairs is for obvious reasons in great demand.

The Sarnia Collegiate Institute and Technical School is nearing completion and is now ready to purchase machinery and equipment for the several departments.

High Speed Belt Driving; How Far Can We Go

By RICHARD JOHNSON, M.E.

HOW much do we actually know about belting except from hearsay? Some of the more common facts we can gather all right from daily experience with them. This experience is not always absolutely reliable. Take, for instance, the good old rule that a quarter-turn belt should be so put that a plumb line dropped from the leaving side of the upper pulley should just touch the leaving side of the lower pulley. There are a good many practical men who would claim that a quarter-turn belt cannot be run unless this rule is very closely observed, and yet, occasionally, where belts are very high speed on short centres, the leaving side of the lower pulley may be some inches away from the plumb line.

Perhaps the most interesting of all is the generally accepted idea that a belt should not be run, at the utmost, at a greater speed than six thousand feet per minute. There are comparatively few who have ever tested to see whether this is true or not. It is a rule that has been handed down from the early days of belt driving, and generally it holds true. The idea is that the centrifugal force is so great at high speeds that the belt will not grip the pulley hard enough. As a matter of fact, however, I know of a fourteen-inch double belt which is running slightly over 7,000 feet per minute, and has done the work satisfactorily for some time.

One well-known type of edger on the market calls for speeds of seven to eight thousand feet right along. As a matter of fact, there are belts running as high as eight and nine thousand feet per minute in this country. It stands to reason that the pulleys have to be reliable and perfectly balanced, and the belt also has to be absolutely even and also well balanced in every way.

A speaker some time ago, before the American Society of Mechanical Engineers, talked about speeds of belts hitherto unheard of—ten, eleven and twelve thousand feet per minute, and one case of a belt which actually ran in use over 11,000 feet per minute. For this purpose the belt, of course, had to be practically perfect, and the pulleys had to be special.

Centrifugal Force

As a belt can make more power the faster it goes, it would follow that if we could run our belts at speeds of 15,000 to 16,000 feet per minute, or more, there would be a great saving in belt bills. But what of the centrifugal force which increases so rapidly with the speed? When you double your speed this force is multiplied by four, and when the speed is quadrupled the force is multiplied by sixteen. This means strain on pulley, strain on belt, and a very powerful tendency on the part of the belt to fly away from the face of the pulley and lose its grip.

But now comes a theory of high-speed belt driving which claims that there are certain efficiencies gained at these high speeds that overcome, and more than overcome, the loss by centrifugal force. Also the strain on the left due to this force is greatly relieved, and also the strain on the tight side of the belt, mainly because the belt is travelling so rapidly that when it leaves the driving pulley it not only travels, but is actually thrown violently against the top of the driven pulley, tending to push it around. Of course, if the belt can push on top, it helps out to a great extent the pull of the belt on the bottom, if the belt could only be thrown hard enough against the pulley and could push hard enough, therefore it would almost entirely relieve the strain on the tight side of the belt, and as a leather belt can stand a great deal of pushing without injury, we would have the spectacle of a belt comparatively small in size transmitting enormous power, not only on account of its speed, but also on account of the fact that it pushes as well as pulls.

Are These Possibilities?

Think of a nine-inch double belt running 20,000 feet per minute and transmitting seven or eight hundred horsepower! It would require only a forty-inch double to run the street car lines of a medium-sized city, and our big mills could easily be run by a twenty-four or thirty-inch double belt. On this basis a portable sawmill could be run, carrying a saw, a planer, a slab saw, a trimmer and an edger. As this place now requires about a sixteenth-inch heavy double, of the best grade, some idea of the saving can be formed.

The investigator of these high belt speeds, who claims to be more or less acquainted with belts which are working often at speeds of eight or ten thousand feet per minute, grows so enthusiastic that he predicts that the limit may range somewhere around twelve or fourteen thousand feet or more before we get full efficiency of our belts.

I am willing to admit from practical experience that on some silk machinery there are small belts, specially and carefully made, which run about eight or nine thousand feet per minute, but they do not last long and it is considered an extremely hard place for a belt. I am also willing to admit that, under peculiar conditions, fancy speeds may possibly be attained by such belts. Lathes are being speeded up, wood-working machinery is running at hitherto unheard of velocities, and no one can predict what will be the limiting speeds fifteen or twenty years from now. While we may reasonably doubt some of the visions of theorists, who only test out and theorize on experimental machinery, it might not be at all bad if experiments could be conducted to show how fast a belt could run under certain conditions, and what the conditions for safety would be.

POINTS ON LIQUID FUEL

Discussing a paper on "Liquid Fuel," which was presented before the Institute of Marine Engineers, in England, Mr. N. A. Anfilogoff mentioned that he would like to give the following practical hints: He said that unless the combustion space is sufficient, one cannot obtain complete combustion of liquid fuel. When the boiler furnace has been designed with an idea of burning coal, and grate area only was taken into consideration, it can be taken that the combustion space would be insufficient for burning liquid fuel weight for weight.

In order to get the oil in the furnace in a very finely divided state, one has to employ the best possible means. Unless the oil is properly heated, filtered, and atomised, a condition will arise in which little chunks of oil will be thrown into the furnace and deposited in the corrugations or even in the back combustion chamber, where they will slowly collect and get converted into porous masses of carbon which will burn away very slowly. Any oil imprisoned in the masses will probably contain a certain percentage of sulphur. This sulphur may get converted into injurious compounds, which, as gases, would travel through the pores of the mass and become deposited or condensed in the coolest part of that mass, which would obviously be the boiler plate.

Following is a tentitive list of machine tools and woodworking equipment which will be necessary for the new technical school at Sarnia, Ont. Tenders will be called for shortly, as this school will be opened sometime in September: 5-lathes, 6 ft. bed, 14 inch swing (one of these will be a tool room lathe with quick change gears; 1 16 inch shaper; 1 drill press; 1 universal milling machine; 1 power hack saw; forges, anvils, vises etc. These will be used in the machine tool section. In the wood working department the following machines will be required, 1 combination cut off and rip saw; 1 band saw; 1 tool grinder, 1 glue stand; 1 electric glue pot; 1 pony planer, and 3 wood turning lathes of different sizes. All machines to be motor driven. In addition to the above a blue print machine will be purchased.

Recent Developments in Mechanical World

Must Know His Own Needs

SPEAKING of "Production Control," what it gives and takes P. J. Darlington sums up the situation in this fashion in a recent issue of Industrial Management.

"To successfully install production control it would seem that the Works Manager must understand the principles involved. He must have a practical working knowledge of those means which have been developed and are available to him for applying those principles and he must have a firm grasp of the needs of his own factory and the objects to be attained.

"He will then apply the principles of production control to his own problems in the simplest and most direct manner, much as the engineer applies his knowledge of mechanical movements, structural stresses and properties of materials to the design of a machine for a specified purpose. The efficiency expert may aid by finding ingenious means and processes, but the proportioning and application of production control to given conditions is the business of the Works Manager. There are too many considerations and conditions to allow reasonable hope of finding a ready made plan.

"Production control is not a new invention or discovery. It is mostly common sense. All successful factories are exercising some measure of production control in some form, although they may not recognize it under the name. A clearer understanding of the principles may help them to extend and perfect their plans."

Making An Invention Pay

"IN EXPLOITING their inventions, inventors must not allow themselves to be tempted through any get-rich-quick schemes," says a writer in Practical Engineer, an English publication. He goes on to say that the percentage of patented inventions that are never exploited on a commercial scale is much greater than that of those that are developed. The undeveloped specifications may not, however, be useless, for they provide a permanent record of some of the enterprises and activities of the inventors at certain periods in their lives. Furthermore, in not a few cases the possession of a few patents has been the means of securing employment for an inventor, even although the inventions were not developed either before or subsequently.

"Inventions may be classified under two headings," this writer continues, "namely, those that are entirely novel in the sense that they provide means for carrying out a purpose hitherto unprovided for, and those which only provide an alternative means for carrying out a purpose already provided for. In the former case, the inventor must strive to determine as many means of carrying out the purpose as he can and have them all incorporated in one or more specifications. He will then be protected from competition from others who afterwards, perhaps inspired by his pioneer work, might think out the alternative arrangements and secure separate patents for themselves. At the same time, it must be understood that two inventions cannot be made the subject of a single patent, but an experienced patentee or patent agent can very often successfully incorporate two or three alternative means into one specification.

"With regard to an invention which is only to carry out the same purpose as something already in existence, the inventor must ask himself the following questions before he spends any money on applications for patents. Has his invention any advantages over the existing method? Will the cost of production on a commercial scale be cheaper or more expensive? If the inventor has any experience in engineering, he will probably be able to answer these questions himself. If not, he should consult his patent agent. It has been written, 'Any fool can invent, but it takes an engineer to knock the invention into practical shape.' "

Drawings For Drop Forgers

ACCORDING to A. Stubbs, who read a paper on drop forging lately, the drawings supplied to drop forgers should show the finished machined part, and the drop forger, when quoting, should be told what machining allowance has been made, and if necessary the quotation accompanied by a sketch showing, in addition to the machining allowance, the amount required for draft of dies and the position where the dies would be halved. The practice adopted by some engineering firms of sending two drawings, one showing the finished machined part and the other a stamped drawing, has much to recommend it. The drop forger with this information before him can not only decide which are the most important dimensions or points to be watched, concludes Mr. Stubbs, but can often make suggestions which make either for economical production or a better article.

Proper Heat Treatment of Dies

THE HEAT treatment of drop forging dies, is perhaps one of the most important steps in the economical operation of a drop forging plant, for nearly all other economies may be nullified by improper heat treatment. On the one hand, careless handling in the heat treatment may spoil the dies and cause a waste not only of the material from which they are made, but of all the labor that has been put into the sinking of the impressions. On the other hand, states the Drop Forger, even though the dies may pass from the hardening room in what may appear to be first-class condition, if they are not of the right hardness and toughness, they will not stand up under the hammers anywhere nearly as long as if correctly treated, and as a result the cost of dies will increase rapidly. Too much attention cannot be paid to the heat-treating department in any plant, and this is specially true in a drop-forging plant where dies are hardened and drawn.

Grinding Twist Drill

TWIST DRILLS, although correctly ground, are often observed to fracture at the edges. This may be taken as an indication of too heavy feed. The speed should be increased and the feed correspondingly reduced. If the extreme edges alone are affected, continues the Edgar Allen News, the speed is too high. If the edges of the cutting lips break down soon after the drill has begun its work of penetration, it is a sign that the angle of lip clearance is too great. The splitting of the drill from the point up to the centre may indicate too small a clearance angle. Unequal grinding of the lips and unequal angles on the cutting edges are productive of many drill failures. Sometimes the hole is larger than the drill, pointing to faulty lip grinding. Sometimes the drill will not centre properly, showing that the angle of the cutting edges is too great. In both cases the strain on the drill and the machine that drives it is intense. Slower drilling and excessive driving power required to do the work are symptoms which, if neglected, lead ultimately to breakage and consequent loss.

New Things in Shop Equipment

NUT-TAPPING MACHINE OPERATING DEVICE

The Key Equipment Co., East St. Louis, Ill., have recently developed an air-operated automatic device which controls the operation of bolt-cutting and nut-tapping machine. When this device is applied to a bolt-cutting machine it clamps the work, feeds it into the die, opens the dies after the thread has been cut, returns the carriage to its starting position, and sets the dies for the next cut. When the device is applied to a nut-tapping machine the spindles are held by an air-operated piston when the taps are full, the rising and falling of spindles are controlled, and the blanks automatically fed.

SECTIONAL FILING EQUIPMENT

The Economy Drawing Table and Mfg., Co., Adrian, Mich., have placed on the market a filing case, manufactured in five drawer sections. The filing case has been designed for the filing and preserving of tracings and blue prints. Provisions have been made so that it is impossible for the contents of the drawer to slide over the top, at the sides, or at the back. Each drawer enters a fully enclosed dust proof pocket separated from other pockets into which other drawers enter. When a drawer is closed, the front comes up against a groove in the frame, so that it is entirely dust proof. The cabinet is built in two sizes, one with drawers 26 inches x 38 inches x 2 inches and the other 32 inches x 44 inches x 2 inches, all in side measurements.

BENCH LATHE UNIT

A rather unique installation of several bench lathes mounted on a bench is being marketed by the Elgin Tool Works, Inc., Elgin, Ill. Several standard bench lathes are mounted on the bench, and in a superstructure, countershafts, jack shaft, shifters, etc., are mounted, while the motor driving unit is placed on the under side of the bench platform. It is usual to mount four lathes on a bench, two on each side of a wide bench, with the superstructure between. A larger (or smaller) number of machines can be supplied per unit. Any regular size of bench lathe can be provided. The motors can be furnished to operate on direct or on alternating current. All belt shifters are operated by a number of foot treadles, and the benches are constructed of kiln dried hardwood. A tool drawer and collet rack is furnished for each lathe mounted on the bench.

IMPROVED AIR OPERATED CHUCKS

The line of air operated chucks formerly manufactured by the American Air Chuck Co., have recently been designed and are now being manufactured by the S-P Manufacturing Co. of Cleveland, Ohio. The improved chucks have a capacity range from 6½ to 18 inches, and are designed to hold work by either external or internal surfaces. They are arranged to be of use in general manufacturing or in quantity production work. The jaws, when used as a universal chuck, are actuated by sector levers. A patented feature permits the air to be shut off from the cylinder without releasing the grip on the work. Should the air supply fail, the chuck can be quickly arranged for use as an ordinary lathe chuck.

PARABOLIC MILLING CUTTERS

After an extended research covering several years, the National Twist Drill and Tool Co., Detroit, Mich., have evolved a new type of milling cutter which they are marketing under the trade name of "Parabolic." The name was chosen as one that represents and characterizes the distinctive form of the teeth. Tests showed that in order that milling cutter teeth be of uniform strength throughout their length, the shape must be that of a parabola slightly modified at the small end, which shape is the one used in the new cutters. The number of teeth in the new cutters corresponds to the number usually found in the conventional fine tooth cutter. This feature was found necessary to obtain an efficient chip clearance per tooth, without an excessive peripheral speed. The cutter is made in plain, side, and end mill types, as well as for special purposes.

STRADDLE MILLING MACHINE

Recently the Newton Machine Tool Works, Philadelphia, Pa., developed a cycle feed straddle milling machine which is now being marketed under the trade name Model C-75. One application of the machine is for facing of crank shaft bearings of automobile motors. It is belt driven and can be connected to an electric motor or to a countershaft. The drive is applied through enclosed gears running in oil. The design provides two spindles, which are mounted in housings having individual end adjustment, which permits regrinding of the milling cutters. The method of operation includes a rapid downward advance of the table, a slow feed while the tools are actually cutting, and rapid upward return.

The machine is arranged to automatically stop at the loading position, which can be arranged to be on a level with conveyor rolls. Provision is also made so that the rate of feed can be altered to suit the material being machined, and other events in the cycle of operations are automatically taken care of. Hardened steel jig plates are provided as regular equipment on the table. The clamping arrangements are all taken care of from above through the medium of a double post beam clamp, that is hinged at one end and is supplied with a central clamping screw operated by a handwheel.

PNEUMATIC RIVETING MACHINE

The Blomquist-Eck Machine Co., Cleveland, Ohio, have recently placed on the market a pneumatic riveting machine that consists primarily of a standard pneumatic hammer mounted on a column and provided with an anvil, the control being through the medium of a foot treadle. The downward movement of the treadle causes the hammer to move downward and at the same time opens the air valve. When the pressure on the treadle is removed, the hammer returns to its top position, this movement being assisted through the medium of a counterweight. With the upward movement of the hammer the air is automatically cut off, and the air supply can be regulated by tilting a cam adjustment at the side of machine, this controlling the movement of the air throttle. The hammer slides within the carriage, and is backed up by a spring at the top which absorbs the shock. While operating, the hammer is rotated by means of a belt passing over a pulley which causes the hammer to revolve. Special anvils are provided if required although there are several standard types.

AUTOMATIC DOUBLE-SPINDLE GRINDING MACHINE

A double-spindle automatic grinding machine designed for the rapid and simultaneous grinding of two opposite parallel sides of a piece has been recently placed on the market by the Gardner Machine Co., Beloit, Wis. This machine has several features distinctly different from the ordinary double-spindle disc grinding machines. The machine is of the continuous feed type, and the spindles are horizontal and are offset in relation to one another. For wet grinding the grinding members con-

st of 24-inch diameter abrasive ring hee s carried in specially designed nucks. For dry work, 24-inch steel isc wheels faced with abrasive are used. he parts to be ground are conveyed by carrier that passes between the grind ig wheels. The feed arrangements of ne work carrier can be adjusted to ake care of various numbers of pieces er minute varying between six to forty. Vork is placed in openings in the car- 'er.

One of the grinding wheels is sta- ionary and the other approaches the :ork up to a positive stop, but main- ains an even and constant pressure gainst the work. The positive stop is djustable, and by it the thickness of 'ork is determined. The thickness of inished pieces can be controlled to with- n one ten thousandth part of an inch, nd in large work the automatic feed- ng device enables a large production o be handled. In grinding the largest vork the machine will handle it is ometimes necessary to operate the con- eyor by hand. Devices for trueing he grinding members are an integral art of the machine, and are constantly vailable for use. Among the many rticles that this machine can handle re, piston rings, ball and roller bear- ng races, adding machine parts, thrust vashers, gear blanks, etc.

AUTOMOBILE-BODY PRESS

A press for the production of an all teel automobile body has recently been uilt by the Southwark Foundry and Machine Co., Philadelphia, Pa. The apacity of the press is 450 tons, and he main ram is located in the lower ase to which is secured four columns. The press is provided with clamping nd stripper platens, and the stripper latten carries four hydraulic cylinders cting upon a forged steel plate, which, n turn has sixty stripper pins 1½ inch- s in diameter. These pins project hrough the clamping platen which is a solid steel casting provided with T- lots.

The top platen carries eight hydraulic acks having 5 in. diameter rams and strokes of 5 inches, these jacks being mployed to accomplish the clamping. This platen is adjustable to accommo- late the various sizes of dies, which it may be desired to employ with the press. The complete operation of the machine is controlled with a single lev- r and this lever operates a valve which subjects the four hydraulic cylinders and the main ram, to a low pressure. As soon as the dies come together, high pressure is applied through the steam operating valve to complete the opera- tion. The clamping cylinders are auto- matically controlled from a low pres- sure filling tank, and are capable of standing a pressure of 5,000 pounds per square inch. The die space of the press is 7 feet by 5 feet. The minimum vertical opening between the platen is 18 inches and the maximum is 4 feet.

WHEEL TRUEING HEAD

The Precision & Thread Grinder Mfg., Co., Philadelphia, Pa., is now marketing a grinding wheel trueing head which not only can be applied to their own Precision Thread Grinder but is quite easily used as an auxiliary trueing head on any thread grinding machine. It is claimed that the device will keep the wheel always in correct alignment with the thread being ground. It is quite possible to dress the V-form on the wheel to a sharp point so as to facilitate the grinding of fine threads. There is no limit to the length of threads that may be accurately ground, because the wheel may be trued while grinding.

The feeding mechanism for actuating the head, has a micrometer dial graduated in thousandths, which enables the attachment to be fed forward sufficiently to make up for the reduction in wheel diameter due to wear and dressing. The grinding wheel is trued by means of two diamonds, which cut progressively and alternately. When diamonds are dull they can be rotated a fraction of a turn in order to present a new point to the wheel. The new point will always be sharp so the diamond can be worn down to its setting. A stop is provided for regulating the traverse of the diamonds and can be utilized for predetermining the amount of flat produced at the bottom of the thread, thus insuring that the amount of this flat will be constant, regardless of redressings and without subsequent regauging.

AUTOMATIC HOB SHARPENING MACHINE

The Barber-Coleman Co., Rockford, Ill., have placed on the market an automatic hob sharpening machine. It has a capacity enabling it to take hobs up to four inches in diameter and four inches long. It can also be used to sharpen formed cutters of sizes within its capacity, and the design was developed with the idea in mind that hobs and formed cutters must be sharpened in such a manner that they will continue to reproduce their forms correctly.

The machine can handle hobs that have straight gashes, and also those that have right or left hand spiral gashes up to 30 degrees of angularity. The indexing mechanism will handle any number of gashes between ten and sixteen, there being seven separate index plates furnished. After each complete revolution of the work the machine automatically takes a pre-determined deeper cut as the work starts on its second revolution.

The machine is driven from a countershaft bolted to the back of frame. Electric motor drive can be used by placing a motor on a bracket bolted to the back of the machine frame. A two horsepower, 1,800 r.p.m. motor is furnished. Power to drive the grinding wheel is applied through the medium of an endless belt running over grooved idler pulleys and transmitted finally to the grinding wheel arbor through spiral bevel gears at the back of the wheel head. The grinding wheel is 7 inches in diameter. The machine is automatic throughout. The weight is about 2,250 pounds.

CRANKSHAFT-CHEEK TURNING LATHE

A rather novel type of special lathe has been designed by the Gordon Form Lathe Co., Cincinnati, for turning all the cheeks of automobile crank shafts simultaneously. The machine is manufactured by the Willard Machine Tool C., of the same city, and when developed for crankshafts of four cylinder motors, is equipped with eight rocker arms, each of which controls a tool held in a block that swivels in the rocker arm, the number of rocker arms corresponding to the number of cheeks on the crank shaft. These arms are located back of the work and swing from an over-arm shaft to and from the crankshaft to suit the contour of the cranks. The rocker arms are spaced to coincide with the location of the various crankshaft-cheeks, by means of collars on the overarm, and guide plates fixed to the main frame of the machine. The guide plates are inserted in the rocker arms below the tool blocks.

Feeding of the work is accomplished by movement of the plate, which is fed by a screw. A gear quadrant connected to the feed screw at the front end of the machine provides a wide range of feeds, from very coarse to very fine. An automatic trip serves to throw out the feeding movement through the medium of a lever, at the conclusion of the cuts across the crankshaft-cheeks. At the completion of an operation, the platen is returned to its starting position by turning a handwheel. The head stock, tail stock and steady rests are bolted to the platen to make one unit and travel as an integral piece with the work.

On account of the wide range of feeds the machine can be used on both roughing and finishing work. Ample chip clearance has been provided between the bottoms of the rocker arms and the platen. The chips fall directly into a chip pan within the machine and are removed through a large door in the front of the bed. Cutting lubricant is led to each tool from a belt driven lubricant pump. The main drive of a machine is through a friction clutch pulley.

According to information coming through to the British Trade Commissioner in Toronto, the general industrial condition in Britain is slowly but steadily improving. Speaking broadly there was a marked betterment during October and the early part of November. That there are many hills yet to climb is obvious, but reports indicate a decided spirit of optimism.

Bigger Things Are Ahead

IT IS HARD to visualize the viewpoint of an otherwise sane business man, who expressed the opinion that the world is about to come to an end, *because we have reached the point where little else can be discovered or perfected.*

This outwardly rational individual went on to tell us that the aeroplane was now an accomplished fact, that the submarine was a commercial success and that trains had reached the limit of speed and economical design.

He also went on to point out other wonderful engineering achievements, such as the completion of the Quebec Bridge. At this point we spoiled his discourse by remarking that bigger and greater problems were ahead of us than had ever yet been solved. Although this man did not hail from Missouri, he requested to be shown, and here are a few of the things we told him:

Orville Wright, one of the authorities on aviation, says the need of to-day is a machine capable of landing at such low speed as to make landing in small, fenced-in areas, perfectly safe.

Elmer A. Sperry, of the Sperry Gyroscope Co., says conservation of our liquid fuel resources is the need of the hour. The present methods, in Mr. Sperry's opinion, are criminally wasteful, and he strongly advocates intensive research toward a permanent cure for such inexcusable waste.

The Hudson Bridge, on which a start will be made in 1922, will be the largest ever undertaken, and its completion will take at least five years. New foundation problems are bound to crop up, and when even such a well-known bridge designer as Gustav Lindenthal, who designed the Hell Gate Bridge, remarks that many new problems will be encountered, we must realize the importance of this latest engineering feat.

Chas. P. Steinmetz, the electrical wizard, says that the breakdown of solid and liquid insulations under electrical stress is the most pressing scientific achievement required in the electrical field. D. W. Griffith yearns for a camera and film which will produce stereoscopic and natural color effects in photography with economic accuracy, while Alexander Graham Bell, the inventor of the telephone, says that alcohol fuel is the hope of the future.

J. G. Vincent, vice-president of the Packard Motor Co., and designer of the Liberty engine, says that the motor industry needs a more efficient utilization of fuel in internal combustion engines, while F. G. Cottrell, famous research chemist, is just as positive that what the world needs is a standard code of language.

Needless to say we convinced our business friend that great times are ahead. If men in these key positions in their respective industries feel the need of such inventions, surely there is a good chance for the brains of the country. If these suggested problems were easy to solve, the men making the suggestions would be only too pleased to present to the world their solution. The very fact that men with such wide experience admit their inability to offer a solution shows clearly the depth of the problem.

So many improvements can be made in all branches of industry and science, that the field of possibility can well be said to be illimitable.

Will Coal Prices Come Down?

THERE APPEARS to be a movement on foot to reduce transportation rates on coal, but railway companies seem to be holding off until coal merchants get rid of their high priced stocks. Another reason for the delay is that some of the railways are owners of coal mines, thus they hesitate to hurt their customers by reducing prices and rates.

In the meantime thousands of cars filled with coal stand on sidings waiting for further moving instructions. People refuse to buy at present prices, except for immediate requirements, so that dealers have still considerable high-priced stock on hand. The mines have in turn reduced their output, this having its effect on the railways' receipts. It is expected that the carrying companies will soon be forced to lower their rates in order to get traffic back to something like normal.

Such close connection between the mines and railways is not always wise, but there is more to the lowering of coal prices than the mere reduction of freight charges. Take the case of the coal miners in Wales, England. The story of their determined strike for nationalization is now history, but since their return to work, and we emphasize the fact that they are now *working*, production has practically doubled. This proves it is not altogether a reduction in wages that counts so much as an increase in production. England is now producing coal on a competitive basis, and sending her fuel to all parts of the world once more.

What can be done in England can likewise be accomplished in Canada and America. Let miners get the spirit of 100 per cent. efficiency, mine owners the proper co-operative feeling, then watch the cost of mining coal come down. Add to this lower freight rates, and fuel will reach a reasonable figure, something it hasn't done for some time past.

There is a crying need for a reduction in transportation prices on more than coal. Railway executives should make a decided effort to offer manufacturers a better rate on the moving of their products. Nothing will speed up business quicker than lower railway charges, and the railways themselves will eventually benefit by the increased tonnage passing over their lines.

Latest News From Various Markets

Steel Mill Output Slowly but Gradually Improving

Tin Plate and Pipe Mills Retain Lead—Small Tools and Supplies Are Active—Ingot Metals and Scraps Continue Quiet —Machine Tools Not Much In Demand

THE GRADUAL improvement in steel mill demand continues. This comes from all sections of the country and from every class of trade. Buying continues to be of the hand-to-mouth variety. The present production rate is approximately the same as it was at the beginning of December, before the lull, but so far, the mills have not reached the 23,000,000 tons rate, which existed during October and November. If the present improvement continues, the rate should get back to the above figure by the middle of February.

The tin plate industry is running at from 70 to 75 per cent. capacity, this really being above the average for this season of the year. Pipe mills are turning out work at about 60 per cent. capacity, and sheet mills at approximately 45 to 50 per cent. Production at bar, shape, plate and rail mills continues to be very light. Taken as a whole, the steel industry is running at about 42 per cent. capacity.

The pig iron market continues dull. Prices have not changed and existing figures do not show much strength. Furnace coke is stagnant, demand being practically non-existent.

The metal market continues very dull. There is some talk of lower iron in the near future, but so far nothing definite has occurred.

Small tools are selling at a better rate. A decided improvement has occurred in this section of the trade, and a further upward movement is expected. In some cases, more business has been closed with firms this year, than all the orders secured during the entire twelve months of 1921. The automotive trade is largely responsible for this improvement.

MILL OUTPUT SHOWS INCREASE; COMPETITION CAUSES SHADING

PITTSBURGH, Feb. 8.—There has been a gradual improvement in demand upon the steel mills since the first of the year, but at a decidedly slower pace than was expected.

There are no particularly outstanding features in the steel demand, which is quite variegated in character and comes from all sections of the country, also from all classes of trade. The demand shows just what is going on industrially. Business is being carried on to the extent that is necessary in a period of readjustment and recuperation, and everything is being done on the most conservative basis. Buyers are not making forward purchases in any case and are not attempting to carry anything like normal stocks. The orders are small individually and the specifications are decidedly mixed. It is strictly what is commonly called hand-to-mouth buying.

Operations of Mills Increasing

As the buying is all for prompt shipment, mill operations show plainly the rate of buying. Almost week by week since the first of the year there have been heavier operations by both the Steel Corporation and the independents, but the Corporation has gained more than the independents and is now operating almost one-half greater percentage of its mill facilities than are the independents. With the increase that has occurred since the first of the year the Steel Corporation has been producing steel ingots in the past two weeks at the rate of about 11,500,000 gross tons a year, while the independents, with their gain, are doing about 10,500,000 tons a year, making about 22,000,000 tons a year as the rate of the steel industry as a whole. This is approximately the rate at the beginning of December, before the lull, when production dropped to below 18,000,000 tons. The rate during October and November was 23,000,000 tons, so that the industry has not thus far, altogether gotten back to that rate. With the recent improvement continued, however, it will do so by the middle of February. As the Steel Corporation has 44 per cent. of the capacity and is producing about 10 per cent larger tonnage of ingots than the independents, it is doing much better than the independents in proportion to the respective capacities.

The best percentage rate of operation is shown by the tin plate branch of the steel industry, which has been running at 70 to 75 per cent. of capacity since the first of the year. Production is really above the average for this time of the year. Prospects are that demand for tin plate for strictly domestic consumption this year will run well above the average, and a record output might easily be made were it not for two handicaps; the light demand for tin plate for export and the relatively light exports of oil in tin plate containers.

Next in point of activity come the pipe mills, which are probably averaging an operation of 60 per cent. of capacity. Pipe mills operations are likely to have a slight seasonal decline in the next few weeks, with an improvement by early spring. Just now the demand for oil country goods is light, but there is still heavy production of line pipe against contracts booked a couple months ago. Demand for standard steel pipe is fairly good.

The sheet mills are operating at an average of between 45 and 50 per cent. of capacity and the present state of the market does not augur much improvement in the near future. Wire mills are running at approximately the same rate. Operations at bar, shape, plate and rail mills are very light. With ingots being produced at 22,000,000 tons a year the steel industry as a whole may be said to be operating at about 42 per cent of capacity.

Steel Prices Generally Firm

While there is very keen price competition in nearly all branches of the finished steel trade the regular or nominal asking prices are not declining, having indeed shown no important decline for over six weeks. The old prices are retained as regular asking prices because small orders can still be booked at those figures, the competition being on orders of particular size. The mills are making concessions for smaller orders, but it is a question whether the extreme concessions are any greater than a few weeks ago. This is a matter that is not tested to any extent because scarcely any really large orders are coming out. Regular prices remain at 1.50c for bars, shapes and plates, 71 per cent. basing discount for standard steel pipe, 2.25c for wire, $2.50 for nails, 2.25c for blue annealed sheets, 3.00c for

black sheets, 4.00c for galvanized sheets and $4.75 for tin plate.

Steel Corporation Earnings

The quarterly report of the United States Steel Corporation shows earnings, after payment of interest on subsidiary company bonds, of $19,612,033 for the December quarter against $18,918,058 for the September quarter. At a glance this looks favorable, as there is an increase of 3.7 per cent., but the shipments in the September quarter were about 30 per cent. of capacity while shipments in the December quarter were about 48 per cent., so that the earnings per ton were greatly reduced. Furthermore, the earnings in December were only $4,967,237, or at the rate of less than $15,000,000 per quarter. Production cost decreased during the six months by reason of the increasing operating rate, also on account of the general wage reduction August 29, prices realized dropped in greater ratio. This year there is further shaving of prices, and still smaller earnings are to be expected for a time. The majority of the independent steel companies have been reporting losses. As a rule they have had two disadvantages by comparison with the Steel Corporation, having had to make various inventory and other adjustments during the past year, which the Steel Corporation attended to before reporting its earnings for 1920, while they do not have as good an operating rate as the corporation, which gets the preference in many cases in the placing of orders on account of the good will it acquired in 1920, by holding down its prices while all the independents made large advantages. Not infrequently the corporation secures slightly higher prices than the independents on this account, apart from getting the preference at identical prices.

Pig Iron and Coke Quiet

The pig iron market continues very dull. Prices are quotable at the same level as a week ago, but do not seem very strong: Bessemer, $19.50; basic, $18; foundry, $19, f.o.b. valley furnaces, freight to Pittsburgh being $1.96.

Connellsville furnace coke is stagnant, there being scarcely any demand, and prices appear still easier, in that two sales for shipment over February, aggregating about 17,000 tons, have been made at under $3.00. Hitherto, prices under $3.00 were applicable only to small prompt lots. As for several weeks past, it is possible to pick up spot furnace coke at $2.75. Foundry coke is in somewhat better demand, though the demand is very spotty. Several large foundry interests are operating at better rates, while there is a little disposition to stock up. Spot foundry coke remains quotable at $3.75 to $4.25 according to brand.

POINTS IN WEEK'S MARKETING NOTES

Montreal merchants, in speaking of the trend in iron and steel, emphasize the belief that the "corner has been turned."

Producers are applying themselves to the securing of business, as they consider that small turnover, even at a slight loss, is better than closed mills.

Requirements are exceptionally light and pig iron production, consequently, is affected, and sales are relatively reduced.

Slow return to normal is exhibited in the gradual increase of production indicated in reports of mill output in the Pittsburgh district.

The tin plate situation is the one bright spot in the metal working industry. Present operations show the mills to be operating at from 70 to 75 per cent. of capacity, and as this is above the normal average for this period of the year, the fact is encouraging.

Total earnings of the U. S. Steel Corporation, for the past quarter were about a million dollars higher than the previous three months, but compared on a production basis, the earnings per ton were considerably lower than for the September quarter.

The local market is spotty. All lines, with the exception of small tools, are dull. The latter mentioned is showing good activity, and further improvement is expected as the year progresses.

IMPROVED CONDITIONS EXPECTED; TREND TOWARDS SPECIAL MACHINES

MONTREAL, Feb. 8.—Reports covering the local trading conditions in the iron and steel business for the last few weeks apply pretty well to the situation that has prevailed during the past week. From no quarter does there come any encouraging news. Before Christmas practically all lines were moving nicely with a very comfortable little increase from week to week. The belief in all circles was that the corner had been turned. It was quite natural to have conditions flatten out during the holiday season, but it was almost the universal opinion that business would pick up again very soon after the new year. This has not been the case, as the month of January has registered the leanest month in this period of depression. Steel plates have been in but little demand. Although no definite reduction in the base price of steel has been announced the present figures are not strong. Merchant bars are also in little demand.

Structural sections have been rather quiet for the last few weeks, but inquiries for this class of material are growing a little more numerous, and in some cases these inquiries have developed into a few small orders. In the city and surrounding district the activity in the building line is rather marked. Every week reports show that building will be very active on the Island of Montreal throughout the 1922 season. There has been a very fair amount of construction this winter, which fact has been the result of a very fair amount of business in the structural steel line. Sheets still continue to be about as active as any department of the steel business. Galvanized sheets have been surprisingly active for the last week or ten days.

Production Cost

In times such as we are at present passing through, prices do not bear the same relation to cost of production as they do in more prosperous periods. Today the idea of the steel producer is to market as much of his product as possible. It is considered that a small turnover, at a slight loss even, is better than no turnover at all and mills closed. For that reason every order is very aggressively sought. This condition of affairs has worked out to the disadvantage of the jobbing house somewhat, as the mills do not hesitate to solicit orders direct, and some mills have a very representative sales force covering the field usually taken care of by the jobber.

To close an order prices are frequently shaded. Thus, the condition of business generally is not in a very attractive position. Matters are not, however, in such shape that they cannot be readily improved, and it is found that there is not much talk in most circles but a sane acceptance of the conditions as they are, which perhaps is the best possible method to be pursued in the present combination of circumstances.

Slow Movement in Pig Iron

Conditions in the pig iron trade remain the same as was reported last week. The drop of two dollars a ton two weeks ago was a very serious blow to the prospects of the producers. There was barely production cost in the higher price, and at the lower quotation, money is lost on every ton sold. The foundries still have no prospects of work ahead of them which would permit them to come into the market to any extent, and even the low levels now prevailing, do not tempt them to purchase. On the other hand the producer is anxious to keep losses at as low a point as possible; it is therefore obvious that orders for any large quantities of pig iron are not attractive. There is no doubt but that the price will advance as soon as normal activities are resumed in the foundries but as that time is still far in the future it is not likely that any immediate advance in the quotations on pig will be made.

Tendency to Special Purpose Tools

The machine tool business is still very quiet. The machine shops are not any nearer the point of coming into the mar-

ket than they appeared to be some weeks ago. For that reason there has been little moving in this line locally.

The shops engaged in strictly manufacturing activities are still operating at away below normal capacity and thus they are not in the market. One point that has been referred to in these columns before is the steady improvement in design that is taking place in all lines of machine tools. There is a growing tendency toward manufacturing special purpose, automatic, and semi-automatic machines and marketing same. Not long ago there was a standard line of general purpose machines that was offered to the buying public. Now there is a wider choice offered the machine man. This increase in the number and variety of machines available adds a few new features to the business of the machine tool dealer, which in times of general activity gives him a better proposition to offer a customer. Here and there an inquiry is received, but orders are only of the smaller kind. At present there is no prospect of conditions improving at an early date. There are many peculiar angles to the present situation and it is not a safe matter to attempt any definite prophecy as to what turn the situation may take in the future.

The small tool business is continuing to be the bright spot in the market. The fairly good demand continues and the volume of business moving in this department compares very favorably with the volume that was passing in the fall months. Prices remain rather steady, but from time to time discounts from the list are announced as manufacturing conditions improve.

Dullness in Metals and Scraps

The non-ferrous metals have also experienced another inactive week, there have been no events that have had any direct action on this market. Prices in some cases are a bit easier but there is no announcement of any drastic price reductions.

The scrap metal markets are still very languid. The inactivities of the foundries influence this market to a great extent. For that reason there is little or nothing to report in this connection.

SMALL TOOLS SHOW ACTIVITY

TORONTO, February 8.—With the exception of the small tool market, conditions are much about the same this week. Steel dealers are finding the going none too good. Some report a fair amount of orders, but generally speaking, things are pretty quiet. The automotive industry seems to be picking up a little, causing a slight stir of activity in steel, but nothing to boast about.

The only comfort, if such we may call it, is that dealers never expect much business at this time of the year. The first two weeks in February are noted for their dullness. What demand does exist on the steel market is general in nature, and scattered so far as territory is concerned.

Machine Tools

There is very little improvement showing in the machine tool field. The market is spotty, with the result you find one dealer fully convinced the corner has been reached, while another may tell you the same day that the bottom has dropped out of his business. The funny part of it is, that both may be telling the truth, but still one cannot describe the market from either of these tales.

If enquiries counted as orders, all would be well, but unfortunately such is not the case. One dealer summarized the situation to a nicety this week when he said, "You know, we have got so used to judging conditions by the ease with which we land orders that we have got the wrong perspective. I thoroughly believe that business can be secured if we go after it hard enough. In fact, I tried out my theory during the past two weeks with favorable and surprising results. The day to take things easy has gone. We must get out and follow every enquiry closely, otherwise conditions will not improve.

"Do not look for any sensational improvement, but I firmly believe that if we make up our mind to dig deep for business, we will find it," concluded our informant.

Metal Market

There is absolutely no change in this section of the market. Conditions are just as dull as ever. When things will pick up is doubtful, in fact one dealer said he was looking for lower priced iron in the near future. This market has had some rude bumps during the past year, but unfortunately we cannot see much hope for improvement for some little time to come. It's a case of waiting for business to pick up. Once let that happen, and the metal market will soon gain strength.

Small Tools

We have at least one cheering story to tell, viz, the small tool market shows steady signs of improvement. One dealer says he has got more business this year already from one concern, than he gathered in from them all last year. Canadian Machinery knows this to be a fact, having seen the orders. All lines in small tools are picking up. Evidently manufacturers allowed their tools to get in such poor shape that before commencing the New Year they felt it good policy to purchase new material in order to speed up production, thus lowering the cost of their product. The demand is general, and orders are coming in from a scattered territory. The orders received are not very large, but in the aggregate they are worth while. The best part of all is that dealers look for still further improvement.

Growing confidence in the ability of the market to pick up, is the only other feature worthy of mention. Dealers in all lines are not discouraged, even if business is weak in some quarters. They feel it will be only a short time before things brighten up, and from present outlook there is no reason to think otherwise.

WELDING LOCOMOTIVE BOILER

(Continued from page 24)

sheet and tapered to a point. Weld the old rivet hole solid as shown in the illustration.

In case mud rings become broken it is advisable to remove a portion of the firebox sheet. Bevel the mud ring from the top, giving at least ¼ inch opening at the bottom of the "V," and reinforce it at the bottom of the mud ring after the weld has been completed on the top portion, afterward applying a patch on the portion of the firebox which was removed. The welding current values for welding mud rings are from 125 to 150 amperes, using an electrode 5/32 inch in diameter. Should the door collar become defective, the defective portion can be removed and a patch applied as in Fig. 17, following the instructions as described for Fig. 8.

Under no circumstances should welding be allowed directly in the knuckles of firebox sheets as shown on Fig. 18. This ruling should be enforced vigorously. It is very important when applying copper flue ferrules to the flue sheet, that, when set and rolled, they do not project out on the fire side of the sheet, so that when the flue is applied the copper will not project under the flue beads. After the flues have been set in the regular manner very good results may be obtained by welding them after having received the second working. That is, if the locomotive is allowed to work its regular turn until the flues are to be reworked the second time, this allows the flues and flue sheets to get a good setting. By so doing it also allows the grease to be burned off the sheet. After the flues are worked the second time, the sheets should be thoroughly sand blasted.

When welding, the top row of flues should be welded first; the second row next and so on until the entire flue sheet has all flues welded to it. It is very essential that the welding be started at the bottom of the flue and worked upward, the weld being finished at the top to secure satisfactory results. It is in this operation that the flowing quality of the electrode is most important and should be given a great deal of consideration. The heat values on this operation vary widely and the operators should use their best judgment according to conditions.

Care should also be exercised on the part of the operator not to apply an excessive amount of metal. If he should do so, the metal will overheat and crack and cause a great deal of trouble. If it should become necessary to reweld a leaky flue which has been welded previously, all the old metal or weld should be removed and the flue worked tight into the sheet, after which it should be sand blasted and welded as formerly described.

News From the Industrial Field

INDUSTRIAL NEWS

Mr. T. J. Moore, Wiarton, Ont., is in the market for a double-end matcher for hardwood flooring.

The Industrial Supply and Service Co., Vancouver, B.C., is in the market for a double end punch and shear, also a nut-making machine.

The Dresden Machine Shop and Garage, Dresden, Ont., are in the market for equipment for their machine and auto repair shop.

Fire caused half a million dollars damage to the Brunette Saw Mill, Sapperton, B.C., on January 29. The saw and planing mills are totally destroyed.

The Red Star Oil Refineries, Montreal, Que., which has a capitalization of $3,000,000, is reported to be planning the erection of an oil refinery on an 18-acre site.

The London Concrete Machinery Co., of London, Ont., has been awarded the contract to supply a 12-inch deep well turbine pump, with motor, to Kitchener, Ont.

Loss to the extent of about $65,000 has resulted from two fires at Port Colborne, Ont. The Maple Leaf Milling Co.'s building and machinery were damaged to the extent of $15,000 and in the other fire the Maple Leaf Hotel, auto garage and various shops, suffered to the extent of $50,000.

The Holden Company, 354 St. James street, Montreal, are in the market for a punch and shear which is to be placed in the factory of the Canadian Brake Shoe Company at Sherbrooke, Que. New tools are to be preferred, but if a second-hand or re-manufactured machine in good condition can be offered for prompt delivery, such a machine or machines will have their consideration.

The city of London, Ont., plans to spend about $4,000,000 on schools this year, according to the extensive programme of building outlined by the Board of Education. The addition to the London Technical and Art School is estimated at $1,000,000, while the programme provides for the erection of new buildings to cost $400,000, including a new 14-roomed school in London, East.

An Incorrect Statement. In the Jan. 26th issue, page 41, we made a statement to the effect that the Ford Motor Car Co., of Canada had acquired the plant of the Bain Wagon Works, Woodstock, Ont. We published this story in all good faith, but we find our source of information was not reliable. John A. Bain, the vice-president and manager of the Bain Wagon Co., says there is absolutely no truth in the former statement, so we take this opportunity of correcting the matter.

The Malcolm Furniture Co., Listowel, Ont., are in the market for equipment for machine shop, small metal working tools, drills and lathes.

Plans for the new Jarvis Street Collegiate, Toronto, Ont., of 32 rooms have been adopted by the school property committee. The building will cost approximately $400,000.

The Canadian Tobacco Growers' Co., Kingsville, Ont., are in the market for equipment, tanks, shredders, and special machinery for the manufacture of fertilizers for tobacco growers.

The public school at Copper Cliff, Ont., valued at $100,000 was recently destroyed by fire. The school will be rebuilt at once, according to Mr. Gallagher, the Secretary of the School Board.

Canadian Pulp and Paper Exports in December, 1921, were valued at $10,325,533, as compared with $14,612,083 in December, 1920. News print and all other classes of pulp show heavier increases in volume over last year, despite slight decreases in values.

J. G. Sullivan, for many years well known as chief engineer for the Canadian Pacific Railway, has been elected president of the Engineering Institute of Canada. Mr. Sullivan succeeds the retiring president, J. M. R. Fairbairn, present chief engineer of the C.P.R.

The Trussed Concrete Steel Co., has appointed Mr. A. C. Riley as manager of the Montreal territory with offices at 323 Drummond Building, St. Catherine St. W., Montreal. Mr. Riley, who was formerly general sales manager of the company, succeeds Mr. G. B. Reynolds, who has resigned.

Algeria is thought to be an excellent market for paints and varnishes in proportion to its population of about 6,000,000. Paints and varnishes are imported principally from France, Belgium, England and the United States, in about the order named, says a United States consular report. In 1919 and 1920 these imports were as follows: In 1919, 69 metric tons of varnishes and 782 tons of paints; in 1920, 253 tons of varnishes and 1,860 tons of paint.

The Swedish Ironworks Association's statistics for the first ten months of 1921 show that the total exports of iron and steel of all kinds amounted to 117,200 tons, which was 50 per cent less than during the same period of 1920, and less than one-third of the normal export. As a result only 21 smelting furnaces were working out of 134, and activity at the rolling mills and other plants was reduced correspondingly. The production of pig-iron during the ten months amounted to 274,000 tons, compared with 376,700 tons during the same period of 1920.

The Georgetown Foundry Co. office Georgetown, Ont., were damaged by fir recently to the extent of $10,000.

A Montreal firm of general contract ors have the contract in hand for th erection of additions to the Chatea Frontenac Hotel. The addition consists o a 20-storey tower containing 200 room at a cost of $500,000.

The Canadian Asbestos Co., which ha its head office, and many branches i Eastern Canadian cities, has announce the opening of distribution plants i Winnipeg to take care of the Weste business.

St. Andrew's-by-the-Sea, New Bruns wick, has been selected by the execu tive committee of the Canadian Manu facturers' Association as the meetin place of the Dominion convention for thi year. The convention will be held on Jun 20, 21 and 22, and after the variou meetings the delegates will travel b special trains on a trip of inspection o the industries of the Maritime Provinces

The Silk Voile Co., a new Bridgebur industry, are looking for additional fe male help, as they are planning to im mediately double their capacity. Thi concern manufactures silk waists, etc and has been established in Bridgebur only a short time. The local manage states that he is having difficulty i getting local help, and has been com pelled to send to Buffalo to secure suf ficient girls to increase his staff.

Shipyards throughout the worl launched 4,341,679 gross tons of ship ping in 1921, or more than 1,500,00 tons less than in 1920, according t Lloyd's Register of Shipping, and 2,803, 000 less than 1919, the record year, bu 1,000,000 more than in 1913. Unite States yards showed a decrease of 1,470, 000 tons of launchings; British yards decline of 500,000 tons, and the tota for yards of other countries a gain o 467,000 tons.

Mr. T. Dick, Junior, president of the National Sand and Material Co., Wel land, Ont., has signed a contract with the Collingwood Shipbuilding Co., for the construction of a sand and gravel carrier, that will surpass anything in capacity that has yet been built on the Great Lakes. Its carrying capacity will be 2,200 cubic yards, which is about four and a half times the size of any boat now in their service. Mr. Dick states that he could have let the contract in Glasgow, Scotland, at a saving of $30,000, but owing to the fact that the boat is to be used on Canadian public works, and municipal works, also in view of the unemployment in Ontario, he thought it best to have the shipbuilding done locally. The Collingwood Shipbuilding Co. are said to be putting on a staff of 150 men this week.

Major-General Sir Alexander Bertram as been appointed treasurer of the Engineering Institute of Canada for the enuing year. Mr. Fraser S. Keith has been e-appointed secretary.

The Collector of Customs for Galt, Ont., reports that the collections there or January amounted to $65,669, an ncrease of $26,082, showing that things ndustrially are improving.

Alexander MacKenzie, who has been ssociated with the Prest-O-Lite Co. for he past four years, has been appointed General Sales Manager of the Canadian National Carbon Co., and Prest-O-Lite Co. of Canada.

L. M. Manley, representative of the Wilmarth & Norman Co., Grand Rapids, Mich., visited the A. R. Williams Machinery Co., a few days ago, the latter mentioned company being agents for W. & M. machines.

J. H. Markel, representative of the Landis Tool Co., Waynesboro, Pa., has been in Canadian territory for about he past five weeks, looking around for possible buyers of grinders of the cylindrical or automobile cylinder type. He s making the office of the F. F. Barber Machinery Co., his headquarters, as this firm are agents for the Landis line.

The value of permits for new buildngs issued by the Architects' Department, City of Toronto, during January, 922, aggregated well over $1,100,000, ractically double the value for the coresponding month last year; but that ells only part of the story, as plans ave been filed for examination, for tructures to the value of another milion dollars.

The General Motors of Canada are eported to be doing a good export usiness, an average of 100 cars per lay being shipped from the Oshawa lant. The Gary Motor Truck Corporaion has secured new orders, and it is nticipated that the Toronto plant will e in full operation before the end of ebruary. The Ford Motor Co. of Canda is operating on a five-day-a-week asis, and it is anticipated that business n 1922 will exceed both 1920 and 1921.

A comparative survey of the industrial tatistics of the Province of Ontario for he three years 1917, 1918 and 1919 has een published by the Dominion Bureau f Statistics. The records show a large ncrease in the number of establishnents, the capital invested, employees, alaries, wages, etc., for the year 1919 s compared with earlier years, although here is a slight decline in the cost of naterials, and in the value of the proluct. Establishments in 1919 numbered 6,438 which shows an increase of 2,100 ver 1917. Capital invested shows $1,-83,161,271, as against $1,335,968,699 n 1917. Employees in 1919 numbered 4.545 compared with 37,132, in 1917. Salaries showed a similar increase, being 20,000,000 over 1917. Cost of materials in 1919 totalled $943,622,018, an inrease of $122,000,000 over 1917. Value f product shows an increase of over 305,000,000 over 1917.

The construction of an ice arena in Montreal, Quebec, will commence early in April.

The American Society for Steel Treating have changed their plans for their sectional meeting, and will now meet at the Hotel McAlpin, 34th and Broadway, New York, on March 3rd.

The ratepayers of Silverthorne, Ont., will be asked to ratify a proposition to raise $161,000 for a new school, together with the site. The cost of the school when completed would be $200,000.

Henry Ford has just purchased the Lincoln Automobile Co. for the sum of $8,000,000. Henry M. Leland, president of the old company will be retained to manage the new concern under the Ford ownership. Immediately following the sale, Mr. Leland announced that all models of cars now on hand would be reduced in price, the cuts ranging from $800 to $1,200.

"The improper use of explosives, caused 31 deaths and 73 injuries during 1920," remarked Lieut.-Col. G. Ogilvie, chief inspector of explosives, Ottawa, during an account of the operation of the Explosives Act of Canada, at a joint meeting of the Montreal Branch of the Engineering Institute of Canada, the Montreal section of the Society of Chemical Industry and the Canadian Institute of Mining and Metallurgy. Sheer negligence, he said, was the cause of many accidents and recklessness contributed its share. "It is very fortunate for us," continued Col. Ogilvie, "that the supply of explosives, other than fireworks, is practically all from Canadian factories. Not only does this facilitate the authorization of the explosives put on the market, but, enjoying as we do the co-operation of manufacturers, we have benefited by their influence over their customers in matters relating to the keeping of explosives."

Tractor exhibitions recently held at Le Bourget, produced rather negative results, writes Assistant F. G. Singer, Paris, in the United States commerce reports. The tests were not held under favorable conditions, as the fields given to the various tractor companies for demonstrations were several kilometres apart, and the companies were not authorized to plough deeper than 10 or 15 centimetres in rather dry, sandy ground, in which potatoes have since been planted. The demonstrations held under such conditions do not seem to have had any practical value. Few tractors are being sold at present, as the French farmer is manifesting considerable conservatism in his purchases. The high cost of fuel is a deterrent to the purchase of tractors, and in fact a number of tractors are now lying idle on the farms, as they cannot be operated profitably. The American tractors have a strong hold on the French market, being superior in quality to French machines, and can easily compete with them as regards prices A 9 to 20 horsepower tractor with a 2-bottom, 14-inch plough, apears to be the most suitable.

A one story addition is to be erected in the rear of the main factory of the Wettlaufer Foundry at Mitchell, Ont.

Exports of Paper from Canada during the first eleven months of 1921 and valued at $69,394,795 compared with $52,-315,475 during the corresponding period of 1920.

While the customs receipts for Oshawa, Ont., for the month of January show a slight decrease compared with those of the previous month, customs officials state that business in Oshawa has been considerably heavier.

The Holden Co. of Montreal, announce that they have assumed control of the Canadian Brake Shoe Co., of Sherbrooke, Quebec, manufacturers of electric steel castings. Mr. N. J. Holden, president of the Holden Co., has been elected president of the reorganized Canadian Brake Shoe Co. The Board of directors of the Holden Co., compose largely the directors of the Canadian Brake Shoe Co. and as the Holden Co. have interests in other plants, machinery is being moved from some of these factories to the plant of the Canadian Brake Shoe Co., in an endeavor to consolidate all the Holden manufacturing activities in one plant. It is claimed that the new, improved, and enlarged facilities of the Canadian Brake Shoe plant for manufacturing, together with the adequate systematic inspection, will enable the Holden Co. to guarantee the quality of their product and also assure prompt delivery. The home office of the Canadian Brake Shoe Company will be that of the Holden Co., in Montreal.

NEW TYPE CONCRETE MIXER

A new type concrete mixer, made in Britain, embodies an interesting departure from the older method of design. In this machine the sand and stone are mixed in the correct proportions, and after being sprayed with water are passed into a cylindrical screen fixed inside the mixing drum and revolving on the same axis. The wet sand and stone fall through the holes in the screen in separate particles and meet a cloud of cement which is blown in from the end of the mixing drum. Every particle thus receives its coating of cement. The mixture is then tossed up several times, and at each revolution of the drum meets the cloud of cement, so that finally the machine delivers a uniform concrete in which the cement is thoroughly transfused through the sand and stone. The flow of cement can be regulated to any desired amount, so that any mixture may be accurately determined. Two sizes of machines are made, the larger being capable of mixing from four to five cubic yards per hour, the energy required being only one horse power.

The manufacture of wood pulp within the Dominion is increasing. The amount exported in the year ending 1913 was 5,862,176 tons. This was increased to 15,389,582 tons in 1920.

Marketing Canadian Goods in the Argentine

By H. POLLARD

HOW can Canadian goods be marketed in the Argentine? Being on the ground floor, so to speak, I think it wise to divide the subject into two sections, and the first viewpoint I will take up is the prospects of business, as I have found them, while acting as a representative for Canadian firms.

I spent some eighteen months down here previously as an employee of an English firm engaged in demonstrating and selling aeroplanes. This is, or was, I had better say, a comparatively new line of goods so far as the Argentine is concerned. Now, as one knows, aeroplanes are not an everyday necessity, and they cannot be sold to anyone, nor with the ease with which one can dispose of hundreds of other things in normal times. The field is limited, but the experience I gained while engaged on this work led me to find out many things regarding the native and the country that one does not discover in a general manner. There is today in the Argentine a field for anyone who has the initiative and energy to go and get business. I saw that it was necessary to know the native, and my journeys into the country gave me many valuable pieces of knowledge.

Being employed with an English company, and having Englishmen around me, I did not at first take any great pains to pick up the language, but used an interpreter whenever required. I very quickly found that this was a nuisance, expensive, and altogether to my disadvantage. After a period I decided to start and look around to see if it would not be possible to act as representative for someone and accordingly took stock of the market, to see where to turn my steps. My decision was that I would go to Canada and look around there first. Now I have been asked why did I choose Canada when I am an Englishman and know so very few people in Canada. The reason is that I think Canada can, if she so desires, market a reasonable share of her goods in this market. Canada has, comparatively speaking, few representatives here, her exchange is better than America, and there is today a decided feeling amongst people here to know more of Canada, and her products. As England and America are already well represented, England having been so for a great number of years in a thorough manner, combined with the decided leaning away from American products, then I chose Canada.

If one studies export figures, they will see that the exports of America to Argentina have gone down tremendously this last year. One of the chief reasons why the Americans gained their increase of exports to this country in the last few years, is because they were the only country able to ship to foreign countries, everyone else being busy fighting in Europe. Deliveries and bad packing have been largely responsible for the falling off in their export trade. The sending of goods that have not been up to specification and just as they were ordered, have also helped tremendously.

Points to be Watched

Now, having opened with these general remarks, I will endeavor to give, in as short a manner as possible, the necessary points to be studied by Canadian manufacturers who wish to enter this market.

To enter into any foreign market without some inside knowledge of that market is folly. The best, and only proper way, is to get this from someone who has had action in the particular country concerned. Paper knowledge is all right as far as it goes, but I myself have got particulars of various things from trade statistics that one can get by the mile, but in actual practice it is much different. Take first of all the article you wish to sell. If it is an article that is already in the country you wish to enter, then you must be prepared to advertise well, sell at a close figure to your competitors, less if possible for the time being and demonstrate it thoroughly. If it is an article with a big demand or one that is a necessity, then for the best results you must be prepared to place stocks in the country.

People in the Argentine will not wait eight to ten weeks for an article that is new, and then go to the trouble of pushing it, unless it is a novelty. Having found if the article is saleable or not, then you must proceed to make the selling of it secure. For instance, if it has a registered trade mark, then you must register that mark first before putting it on the market. Take, for an example, an article called "Canada." This name must be registered, and one registration is good for ten years. Now the object of this is, if you do not register the name then, anyone who cares can do so and he has the power to stop you from selling that article for ten years, unless of course, you care to pay him whatever he likes to ask you for allowing you to sell in the Argentine.

Many cases are on record where huge sums of money have been demanded by men who have taken out a registration for an article in their name, then when the article has been put on the market have asked for payment or closed up the sales. I know of more than one instance where this has been done, and the amount paid for the "patente," as is is called, has in some cases been enormous.

Question of Distribution

Next to be arranged is the order in which you are going to distribute your goods and who shall do it. Some articles can only be sold by demonstration. For instance, you could not expect people to buy an everyday article from a catalogue without a sample being shown to them. You do not expect to have samples, nor are you expected to send samples of large pieces of machinery which may be for special purposes. A good technical man and illustrations are quite sufficient. The question of what you should send, and how much, must be determined after carefully weighing the following points. What is likely to be the demand, amount of money invested, necessity of sample for clarity of explanation, competition in the Argentine, that is, the stocks existing in the Argentine.

Then comes the all-important question of how to pack and ship. Good packing is the essence of success to a successful export trade. The obtaining of an order is in many cases dependent on the firm's previous packing. Many buyers today will not change firms because they get their goods packed so well, and they arrive here in good order. I know of firms who would not change, no matter what inducements you offered to them, because all their goods arrive in first class order. Others have had to spend considerably more money than they had allowed for, in fixing the goods up so as to be able to sell them. You cannot pay too much attention to this question. It will in many cases bring repeat orders and always creates for you a friend. In preparing shipping documents it would appear from my experience that there is not much known regarding this point in Canada. In the first place you need the following documents.

(1) Ocean bill of lading giving marks on case, weights net and gross, volume of case, and the name of person it is destined for. Two of these are needed, but one must be stamped and signed by the Argentine consul.

(2) Insurance certificate. While this is not necessary for clearing the goods at this end, it is useless to expect to get a claim settled if you have not got one. It is also necessary to clearly have stated on this what you have insured the goods against.

(3) Certified invoice. This must show the price and weight of each individual item, but does not require to be stamped by the consul. As I have had considerable difficulty myself in this direction I am going to, in a later article, show a specimen set of documents to the Canadian Machinery for publication.

Another Important Detail

Another important detail is to study the man you are going to sell to. The personal point is a very great one in the Argentine, and there are any amount of splendid salesmen at home in Canada that would never get on at all in the

(Continued on Page 43)

MARKETING CANADIAN GOODS

(Continued from Page 42)

Argentine. There are today any amount of people who have the impression that the South American is more or less the kind of man you can push anything on to at any price. Let me dispel any such notion at the outset. The Argentinian today is a very well educated man, (speaking of the business classes) who is as keen and alive to the other parts of the world as you are. His geography may not be as extensive, but he is far from being the fool that so many people have tried to make him out to be. Just because a man has different habits and customs to you does not make him one bit different when it comes to business. The business man of the Argentine today is a gentleman to his finger tips, and expects to be treated as such, because he treats you always as one.

You must keep your word to him at any cost and by so doing you have fought your biggest fight in the battle for his confidence and his business. Make a friend of a real Argentinian and you have made one who will stand by you through thick and thin. In expressing himself he does not employ the same direct language that you are accustomed to using, but has a way of his own, and he does not like to be disturbed from it. It is very annoying and trying at times, but you must accustom yourself to it if you wish to keep in business down here. You have your little peculiarities, and so has he. You are right in your way, and so is he, although each may think differently.

If that is the case, then it is better to think alone and not give public voice to your opinion. To do business in this country one must adapt himself to the country, study their laws, ways, etc., and do business as far as possible as the Argentine wants to do it, and not always as you think it should be done.

The Argentinian, when asking for an article, wants that article, and not one just as good or better. He has learned by experience what the value of an article is from a selling point of view, and to take him an article and say that it is just as good or even better, though the price may be much cheaper, you will have a poor opportunity of selling. In fixing your selling price do not try and get as high a price as you think you might be able to get. Remember, you are not the only firm in the world, so be satisfied with a reasonable profit.

In closing I would say, in short, that for success here you must look after price, shipping and packing. If you can arrange all these satisfactorily then you are well in the Argentine market if you are manufacturing an article that is worth buying.

Over 500 engineers from all sections of Canada will assemble in Montreal from Jan. 24-25 at the annual general meeting of the Engineering Institute of Canada.

Scotland's Industry and Trade During 1921

By G. B. JOHNSON
Trade Commissioner at Glasgow

SPEAKING of Scotland's industry and trade in 1921, Trade Commissioner G. B. Johnson says that last year was a disastrous one for the steel trade in Scotland as it was in America. "It is perhaps not generally realized," he continues, "that Scotland is the largest producer of steel of any district in the British Isles. The ingot output of Scotland last year was 2,077,000 long tons. The next in order was the North-East coast of England with 1,958,000 tons, with South Wales and Sheffield following. Scotland has, however, specially cultivated the trade for high-class Siemens steel such as is required for boiler-making, shipbuilding, bridge-building, and general engineering purposes. The Continent, on the other hand, has continued to produce Bessemer quality of steel.

"The steel industry is of such national importance as was perhaps only fully realized during the war when no industry played a more important part. The great demand for war material and the necessity for extensions have enabled the industry to greatly increase its power of production. There are many plants in Scotland to-day which embody all the latest developments, and can compare favorably with any steel plants in the world, although they are not on the gigantic scale of some to be found in the United States and the Continent. The prosperity of the country largely depends upon the steel trade being maintained at the highest standard in all respects, for upon this industry in Scotland and England rests the country's position as the greatest ship owning and shipbuilding nation, as engineers in the building of railways and bridges in this and many other countries, and in the production of machinery.

Foreign Competition

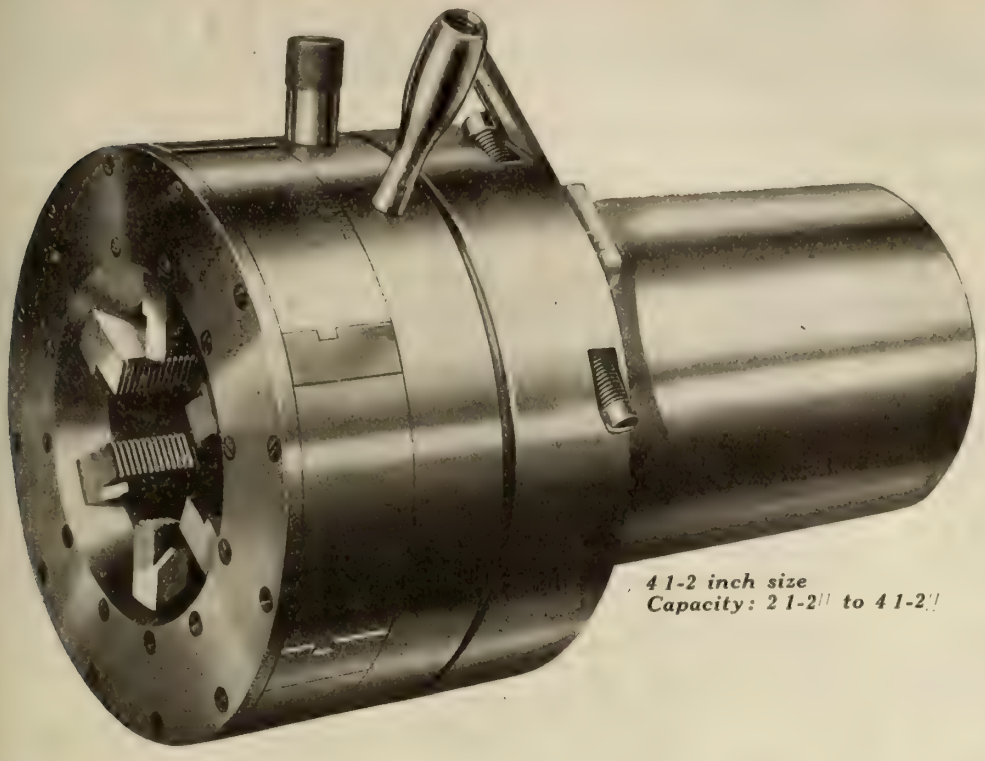
"The year commenced with falling prices and increased foreign competition through falling exchanges. In March the coal strike upset all the calculations of the makers, and plant after plant was closed down as stocks of coal became exhausted, and orders which might have been secured for the West of Scotland were picked up by Continental makers. In August when the strike was well over and coal supplies again available, prices were reduced, boiler plates to £19, ship plates to £14, and sections to £13 10s. per long ton. This action so reduced the difference between Continental and British prices, and Continental makers were so booked up with orders, that a more hopeful feeling prevailed until at a meeting of the Scottish and English Steel Association, it was found impossible to agree to a uniform basis of prices for the two districts. Since that time Scottish producers have been competing with English in the other's territories, and with each other, and some very low quotations have been made. In the export trade, competition from the Continent has been much less severe during the last three months.

Machinery and Engineering

In this branch of industry the past year has followed the course of trade in general. The marine engine section, the most important and in regard to which the Clyde is so pre-emient, is so closely allied with Clyde shipbuilding, that the fortunes of one tell the tale of the other. There are many other important sections such as the building of locomotives, mining machinery, and machinery for the manufacture of rubber goods, sugar and paper. An important firm who specializes in making rubber and paper machinery recently informed the writer that the year just past was the worst in their long history.

'As far as the shipbuilding industry on the Clyde is concerned, it has suffered a period of stagnation during 1921 from which there seems to be no immediate escape. As one expert says, it has been a year of cleaning off old contracts, and new work has been very slow in coming forward. The general depression has of course, been mainly responsible, with the result that ships have been laid up by the hundred in all parts of the world through lack of demand for cargo space and new ships have not been wanted. Continental competition has also been severely felt, mainly in the departments of repair and overhaul, as their quotations were usually lower.

"It was realized early in the year," continues Mr. Johnson, "that the demand for new ships apart from other reasons, would not revive until costs of production more nearly approached the market value of ships. Then the attempt to reduce costs, including wages, resulted in numerous strikes, one of which, that of the shipyard joiners, lasted nine months. Whether these strikes opened the eyes of both sides in the dispute to the urgent necessity of introducing good will instead of strife into their mutual relations in order to save their industry, or whether the loss of contracts to the continent and great unemployment demonstrated the necessity of lower costs, it is a fact that there is a new spirit of give-and-take in this industry as well as in others. Wages have been substantially reduced, profits have vanished, the cost of steel is lower, but it is said there is even yet too wide a margin between quotations and the prices which shipping companies can pay and earn dividends.



"The awarding of three of the four super-Hood battle-cruisers to Clyde firms, together with most of the machinery, was a bright spot in the year's gloom; but the position of affairs brought about at the Washington Conference quickly put an end to hopes in that respect. It is perhaps not remarkable especially, but at any rate is worthy of note, that the cancelling of these contracts by the Admiralty was received in such good spirit as was the case. The general relief at the savings to the tapayers of such large sums as these ships involved easily outweighed any disappointment at the cutting sho. of local benefits.

"The complete absence of anything in the nature of parochial spirit in the newspapers in this regard was conspicuous. The circulation locally of £30,000,000 of money, which these ships were expected to cost, would have relieved unemployment to a useful extent. But as a gentleman closely concerned with this industry remarked to the writer, the building of the warships was, after all, only an item, although an important item, in Clyde shipbuilding.

Motor Ships

"An interesting feature of the year was launching of nine motor ships. The internal combustion engine has made great headway at sea, as is indicated by the fact that at present there are several hundred ships so equipped. Hitherto this type of engine has not been applied to passenger-carrying ships, but one of the nine above mentioned, and the first of its kind, is the motor passenger liner, the Domala, built for the British India Steam Navigation Company for trade between London and India. This liner can accommodate 140 passengers in addition to 11,000 tons of freight. Her two oil engines develop 4,660 h.p., and her fuel consumption at 13½ knots is estimated to be 20 tons of oil daily. This ship sailed in December from London on her maiden voyage. She is equipped to carry enough oil for the round trip—a decided advantage compared with a coal-burning ship whose bunkers have to be replenished several times on the same journey.

"No immediate improvement in shipbuilding can be discerned, but it should be remembered that building ships is not a basic industry, and any improvement must follow a demand for cargo space, which will come from a trade revival requiring the movement of commodities. The launches on the Clyde in 1921 numbered 408, comprising a tonnage of 512,137 with an indicated horsepower of 493,530."

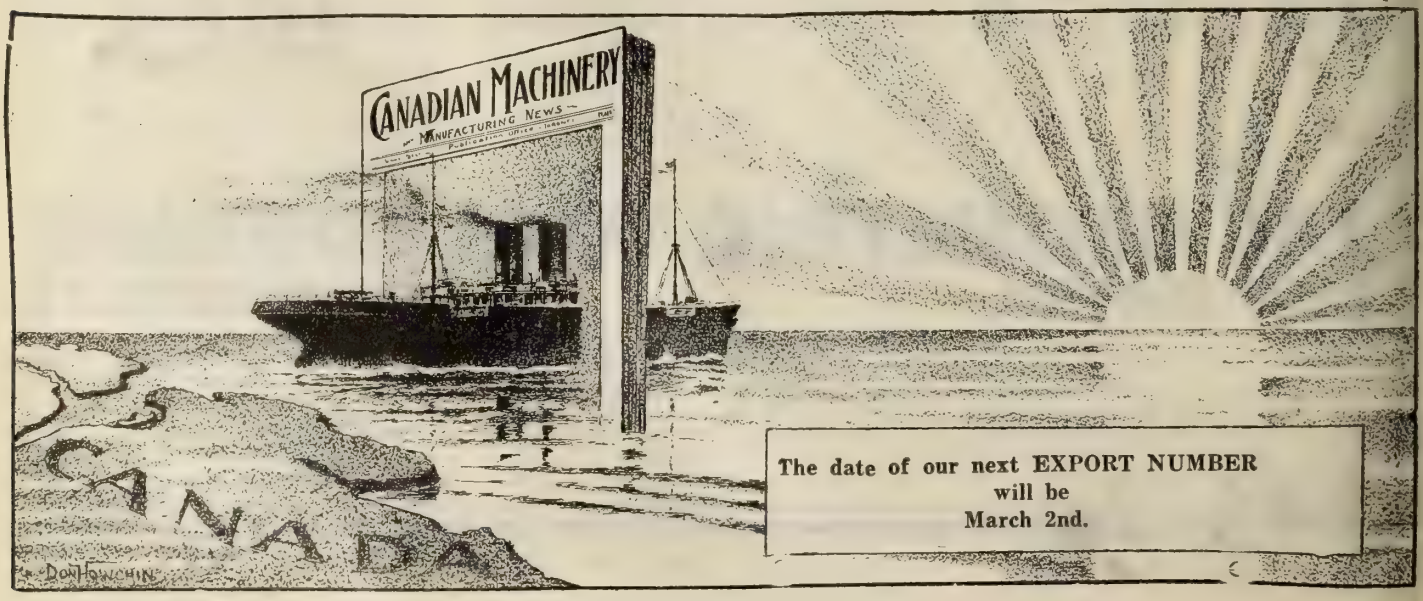
Advertisements under this heading will be inserted once free of charge. Readers are invited to use this department when in need of equipment. Replies may be sent to box number, care of Canadian Machinery, if desired.

MACHINERY WANTED

WANTED — A LATHE AND GEAR CUTTER. Must be in good condition. Advertiser desires to get in touch quickly with any person who is able to offer same. Apply Beaver Machine Shop, 1110 Center St., Calgary, Alberta. (c5mlg)

THE FOLLOWING MACHINERY IS WANTED by one of our foremost technical schools:—

5 lathes, 6 ft. bed, 14 inch swing (one of these will be a tool room lathe with quick change gears).
1 16-inch shaper,
1 drill press,
1 Universal milling machine,
1 power hack saw,
forges, anvils, vises,
1 combination cut off and rip saw,
1 band saw,
1 tool grinder,
1 glue stand,
1 electric glue pot,
1 pony planer,
3 wood turning lathes of different sizes, all machines to be motor driven,
1 blue print machine.



Please address all replies to Box 862T. Canadian Machinery.

MACHINE WORK WANTED

MACHINE WORK WANTED FOR LATHES, shapers, milling machine and planer, etc. Hourly or contract basis. Prompt delivery. W.H. Sumbling Machinery Co., Toronto. (etfm)

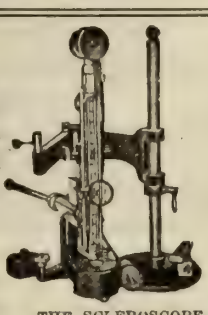
EQUIPMENT WANTED

CAFETERIA EQUIPMENT — RANGE, STEAM table, glass shelving, urns, Cash register, etc. Must be in first class condition. Give description and prices. State where may be inspected. Box No. 801L, Canadian Machinery.

The date of our next EXPORT NUMBER will be March 2nd.

HINTS TO BUYERS

For Hardness Testing



in shop and laboratory use the

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

For Information of Unusual Importance

(Advertisement)

You can't help noticing the good qualities of

Pratt & Whitney Taps

Their free cutting qualities, their extreme accuracy and their extraordinary ability to outlive others distinguish them.
The con-eccentric relief—a distinctive P & W feature—is the secret of their goodness. One-third of the cutting edge is concentric. The remaining two-thirds has eccentric relief. Taps can be sharpened at the only correct point—on the face of the cutting edge. Sharpening in no way affects their size.

Yes, they cost a little more than some others, but they're well worth the difference. Carried in stock as are all other P & W Small Tools at our sales offices and agencies as listed.

Confidence

Fifteen years and more is not an unusual length of service for Bristol's Recording Instruments. In many industrial plants there may be found recorders which have been in constant use for this length of time. We are proud of these "old recorders"—they stand for just the sincerity and reliability we have endeavored to put into them.

Time and Service Tested

TRADE MARK
BRISTOL'S
REG.U.S.PAT.OFFICE

Recording Instruments

have earned the confidence which could not be gained otherwise. They have proved beyond any doubt that the performance in service is all and more than we claim.
The ever growing demand for recording instruments is shown by the fact that a little over thirty years ago the only recording instrument was a pressure gauge, while now our line includes: Recording Instruments for Pressure, Vacuum, Temperature, Electricity, Time, Motion, Speed, Humidity, etc.

Get copy of information Bulletin 1-303, telling about this line of Recorders.

Filtration of Oil Saves Power

Faulty lubrication means loss of power on each of thousands of bearings in your plant. Fuel must be burned and current used which *gives no return for its cost.*

Perfect lubrication necessitates clean oil. Filtration is the only means of cleaning oil and conserving its full lubricating quality.

Bowser Oil Filtering Systems do this by removing all water and dirt from your oil. The same oil can be used indefinitely—and will always give the same clean, cool lubrication.

The Bowser Systems save the cost of fuel consumed in generating that wasted power, lessen machinery depreciation by reducing friction and cut your oil bill in half.

Ask Bowser Lubrication Engineers.

HEALD

Are You Getting All the Possible Work in Your Vicinity?

Machine and auto repair shops can no longer rely on a miscellaneous set of small tools to maintain a successful business. To-day their equipment must be such that no matter what the job is, it can be handled properly and at the least expense if they are to get all the potential work in that locality.

This is clearly demonstrated by an article in "Motor Age" the issue of October 27, 1921, which says:

"In a small town of Nebraska of less than 2,000 people, there is a dealer who has one of the most completely equipped shops ever noted in automotive repair work. This shop is prepared to do anything except cutting gears.

"There are two lathes in it, several drill presses, a CYLINDER REGRINDING MACHINE, welding outfits, forge arbor presses and other equipment too numerous to mention.

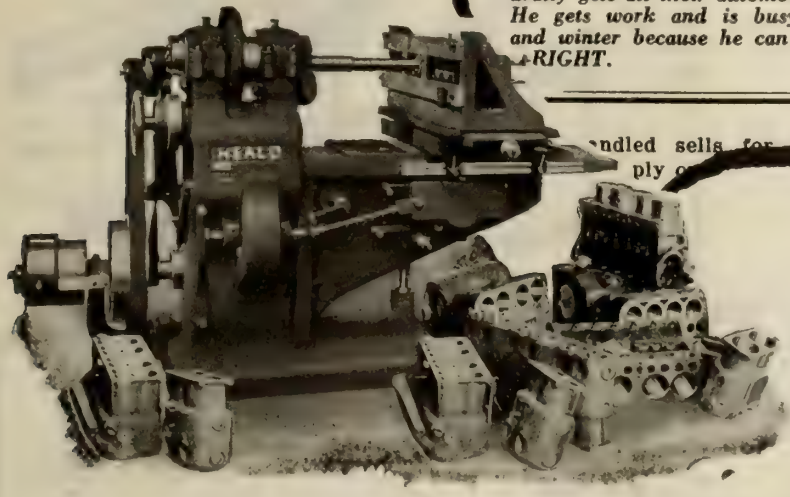
"Naturally the question comes up, 'Why all this equipment in so small a community?' It is for this reason: In this part of Nebraska there are many tractors. The county is supposed to have a car for every four persons. There are farm trucks, too. This dealer knew that all this equipment must be maintained properly. He knew that there were HUNDREDS OF CYLINDERS THAT WOULD NEED REGRINDING EVENTUALLY, so he installed the grinder.

"Work is sent to him from a radius of hundreds of miles. The shop does a lot of miscellaneous work for farmers such as pointing and sharpening plough shares, making brackets for wagons, welding broken parts, etc., with the result that the farmers are sold on the place and naturally bring their cars and trucks there for repairs. THE SHOP IS BUSY SUMMER AND WINTER. It is true that new car sales in this territory are not what they might be, but the shop is making money. The dealer knew the potential service work of the community and then tooled up for it. He got it."

Needless to say, a concern with such foresight and business management would use equally as good judgment in the choice of its machines and therefore they selected a HEALD.

There are many repair shops all over the country that are not getting the potential business in their vicinity because they are not equipped for it. Especially is this true in regard to cylinder regrinding which is fast becoming recognized as a necessity if the motor is to give maximum results. The shops that pride themselves on being able to turn out a complete perfect job must equip with a HEALD unless they can secure HEALD finish from some nearby grinding shop.

Why This Shop Installed a Cylinder Grinder



WHEN one thinks of a cylinder regrinding machine he hardly can imagine one of these expensive machines in any but a large town machine shop or in a good-sized service station.

Yet there is a dealer in a small town—less than 2,000—of Nebraska who, among other machines like engine lathes, drill presses, grinders, etc., has a cylinder regrinder. On this machine he can handle any engine block, from a Ford to the large blocks of the gigantic tractors operating in that territory.

Why a cylinder regrinder in such a small town? Just this:

This dealer knew the potential repair work in that territory. He knew by equipping his shop as completely as the large machine shops of the country he could handle any class of work, except gear cutting. He does work for the farmers on their agricultural implements and as a result naturally gets all their automobile work. He gets work and is busy summer and winter because he can handle it RIGHT.

Motor Age Oct 27

The above facts will be inevitable this spring when cars are overhauled and now is the logical time to write, wire or 'phone.

Same Motor: *different work, different brushes*

Columbia Data Sheet Service Solves Your Brush Problems.

Write the address below.

C N C

Brush requirements vary with the application of the motor or generator.

What is correct for a motor or generator in one case may be entirely wrong for the same motor or generator in another.

Only careful analysis of the service conditions will assure the best results from each unit. The investigation and analysis of these conditions is the function of Columbia Data Sheet Service.

At your request Columbia Brush Specialists will examine your machines—each machine individually—and ascertain exact conditions of operating.

They pass these facts to our Board of Engineers, which analyzes the facts and specifies correct brushes for each machine. The Columbia Pyramid Brushes recommended are guaranteed to give satisfaction in service.

You are invited to avail yourself of this service. It is at your command, whether you have one unit or a thousand.

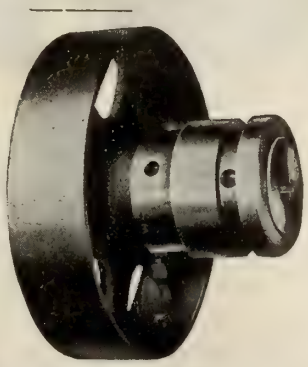
THE JOHNSON FRICTION CLUTCH

Friction Clutches From Stock

Johnson Clutches, both single and double, can now be obtained from stock in our standard slow speed type to fit all common shaft diameters and all standard pulley bores, within the range of light and medium horse powers that we cover.

State definitely —



Just what the clutch must drive.
Actual maximum horse power.
Speed of clutch shaft.
Diameter of shaft.
Diameter, width and bore of pulley.

We Will Select the Proper Clutch and Make Immediate Shipment on All Ordinary Requirements.

Friction Control Means Better Machinery

And the Johnson Clutch is supreme among friction clutches. Adopt it as your standard — always dependable and always promptly obtained.

Complete engineering service to consult on your problems and to handle special installations of any kind.

Operators Prefer New Air-Tight Blast Gate

Detroit, Mich.

Air-Tight Blast Gates are giving very good satisfaction, and our operators prefer them to either valves or cocks for the air line.

LINCOLN MOTOR CO.

There are many reasons why—Low first cost and upkeep—Easily and quickly operated—Afford full area of the pipe.

An ideal substitute for heavy, cumbersome, expensive and slow-acting gate valves and stop cocks.

This New Air-Tight Blast Gate is made in sizes from 2 to 16 inches, threaded and flanged. Descriptive circular 210—T gives detail dimensions of all sizes. Write for copy.

NEW AIR-TIGHT BLAST GATE
Light, Strong, Compact, Inexpensive, Quick-Acting

"Air is Free, but not Compressed Air."

A Wiping Cloth Cut to Useable Sizes

and not a thing on it to scratch—

Button, Button, who's got the Button?

ALL buttons, hooks, seams and other obstructions are carefully removed from all materials used for SUNCLO Wiping Cloths. For the user of SUNCLO there is no fear of having the finest surface scratched or marred.

The SUNCLO TAG assures:

A Wiping Cloth that is cleansed and sterilized by the most efficient and scientific methods.

A Wiping Cloth that is soft and absorbent.

A Wiping Cloth that is standardized as to quality.

A SUNCLO Wiping Cloth is a revelation beside the old unsanitary, filthy rag, that probably came out of some dingy junk shop to you.

All those who boast of a modern plant, should first make inquiries as to the kind of Wiping Cloths used. If it is the kind used by some of the most progressive manufacturing plants in Canada—SUNCLO—it's all right.

Nicholson File Company

Port Hope - [illegible] - Ontario

The twenty-horse-power induction motor with end cap removed showing the self-aligning ball bearing. Note that the ball bearings are contained within simply constructed bearing head brackets with liberal lubricant chambers, which are sealed on both sides by end caps. These end caps are fitted close to the motor shaft and are practically proof against leakage of lubricant, as well as the intrusion of moisture, dust, lint, grit and other foreign substances from without.

The use of ball bearings in electrical machines—

has been a continuous growth and is fast coming to be considered vital to the best mechanical practice in the design of electrical machinery. So marked is this fact that today the leading manufacturers of electrical machinery have a standard line of ball bearing motors.

Self-aligning ball bearings marked **SKF** are particularly adapted for motor uses and are so nearly frictionless that wear is practically eliminated. This insures perfect rotor alignment almost indefinitely with a constant high efficiency air gap for maximum motor life. And because they are wear-free, the bearings run cool and require a minimum of lubrication and attention.

The engineering experience of our organization is at your disposal. You are urged to submit your bearing problems to us for careful and impartial consideration.

Four Reasons

Why Manufacturers Choose the MacLean Technical Newspapers to Carry Their Message to the Buyer

1. Technical Newspaper, with special stress on the syllable **news,** is the correct term to apply to any of the publications of the MacLean Technical group. Each issue of Canadian Machinery, Canadian Foundryman, Power House and Marine Engineering represent the work of a widely experienced editorial staff—a staff of practical men who are well versed in present-day requirements. They keep the employer and his workroom executives in close touch with the latest ideas in industrial practice and at the same time give them interesting news of the trade. Workmen with an ambition to advance find the MacLean technical newspapers a sure means of success. The papers serve a broad field and serve it thoroughly.

2. By subjection to the rigid test of an audit by the Audit Bureau of Circulations, each of the MacLean Technical Papers not only proves its circulation but tells definitely just what kind of people it reaches. Such being the case, specimen copies, "bulk" subscriptions and subscriptions long in arrears are not taken into consideration. The paper with a high aim and nothing to conceal is invariably connected with the A. B. C.

3. Enrollment in the Canadian National Newspapers and Periodicals Association is another instance of progress and square dealing. It demands the following pledges:

"To consider first the interests of the subscriber."

"To work for truth and honesty in all departments, and among other things to supply advertisers with full information regarding character and extent of circulation."

4. Rigid adherence to the practice of progress. service and fair dealing has resulted in the MacLean Publishing Co. becoming the largest disseminators of technical information and trade news in the British Empire. To-day the Company publishes, all told, sixteen technical and trade newspapers and magazines, and besides the immense office of publication at Toronto, offices are maintained at Montreal, Winnipeg, Vancouver, Chicago, Boston, Cleveland, New York, and London, Eng.

Norton Alundum Elastic Cutting Off Wheels Are Indispensable For Tool Room Use

How often have you wished you had a grinding wheel for cutting off hardened or high speed steel, for salvaging drills, or for doing some special tool sharpening work?

We are manufacturing here Norton Alundum Cutting-off wheels up to 12″ in diameter and 1/16″, 3/32″ or 1/8″ in thickness, designed for just such operations.

We are equipped to supply you promptly in any quantities and in abrasive, grain and grade to give you maximum service.

If you have not seen for yourself the cutting speed of these wheels and demonstrated the advantages to your own satisfaction, order one for trial and test its value. If you will mention the kind of work you have, you will enable us to select the best wheel for you without any delay.

Any grinding problem you have, no matter what it is; we would like very much to help you solve it.

How to Use Milling Machines to Best Advantage

Machining Journal Box and Top of Special Table—Milling Large Chilled Rolls—How Gang Cutters Speed Up Production—Fixture Design Must Be Carefully Planned

By J. H. MOORE

SOME TIME ago the superintendent of a large manufacturing plant in Canada developed a case of walkitis. For days at a stretch he paced up and down the aisle of a certain department, always pausing at a group of milling machines, which seemed to be doing their utmost to produce parts as quickly as possible. "I know those tools are good for more production," he could be heard to mutter, and off he would start once more on his journey of thought. Later the chief draftsman was called into the superintendent's office, the upshot being the tool room soon had a brand new set of blueprints showing a special fixture and cutter which had to be made for the milling machines in question.

About two weeks transpired, and the same superintendent walked past those machines once more, but with a smile on his face, for production had increased over 100 per cent. "I knew they had it in them," he chuckled, and off he went to seek fresh fields of endeavor.

This story is told simply to push home the fact that existing equipment can often be made more efficient by a little careful thought. The writer has witnessed on many occasions a good sized milling machine busily (?) engaged, cutting a ⅜-in wide keyway, when that same tool should have been turning out much more important work. Even small shops should plan their milling work just as carefully as larger plants, though of course on a smaller scale. They cannot afford to spend a great amount of money on jigs, special cutters, and so on, but they can improve, at small cost, the clamp or vise method of holding. They can also set up the parts in gang fashion, doing many pieces practically in the same time as it would take to complete one.

At a Hamilton, Ontario, plant, they wanted to mill keyways on a number of shafts, and at first started to mill them one at a time. This method being too slow, they arranged twelve shafts on one jig plate, milling the lot by the aid of gang cutters.

The jig was simply a series of "V's," six shafts resting at each side of the jig plate. One strap held six shafts in place and the operator milled a batch of six, while he was loading the other end of the jig. The complete fixture cost a little over $12, but it made the difference between a profitable and an unprofitable job.

Study the Part

Just because a certain piece is at present being machined on a planer, or shaper, is no reason why it should continue to be completed on such a machine. Perhaps you would often like to use the shaper, or planer, as the case may be, but this particular piece prevents your doing so. How about the milling machine? Have you ever stopped to see if the operation could be switched?

If not, now is the time to do it. By all means bring the chief draftsman into the discussion. He is used to visualizing ideas, and will be able to offer valuable suggestions regarding the construction and simplification of any fixture. Tell him frankly your manufacturing troubles, so that he can hit

We are indebted to the Kearney & Trecker Co., Milwaukee Wis., for the use of Figs. 1, 4, 5, 6 and 7, and to the Browne & Sharpe Co., Providence R. I., for the use of Figs. 2 and 3.

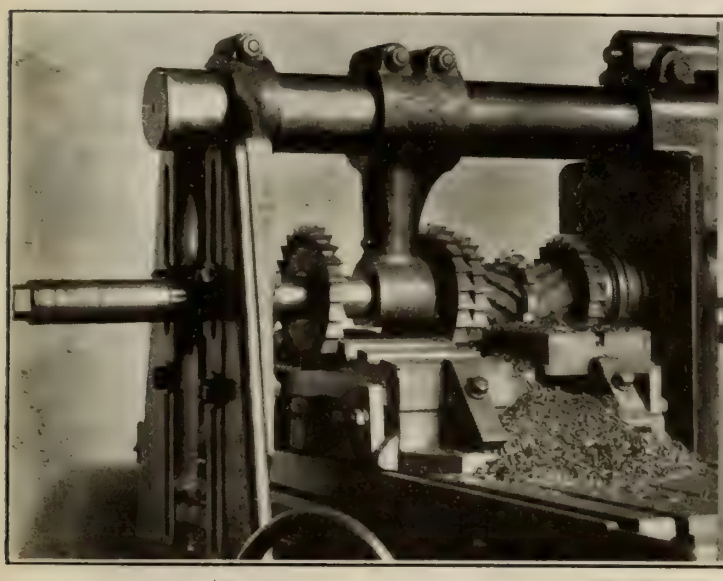

Fig. 2.—Milling top of special table.

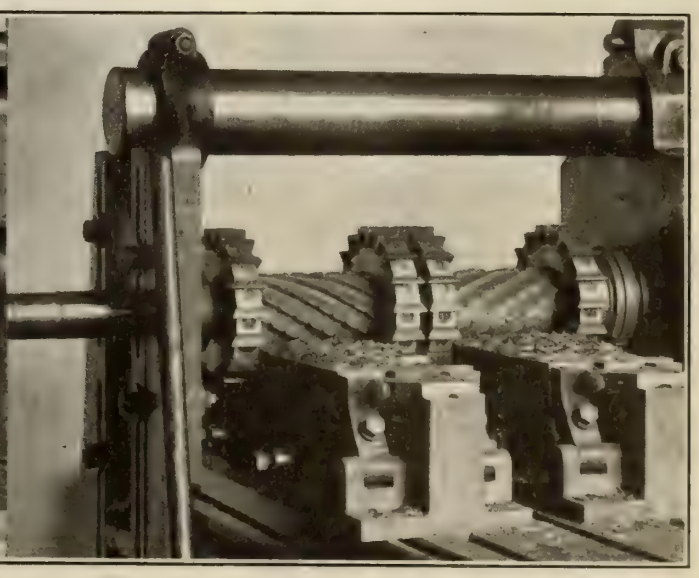

Fig. 3.—Showing the advantage of gang milling.

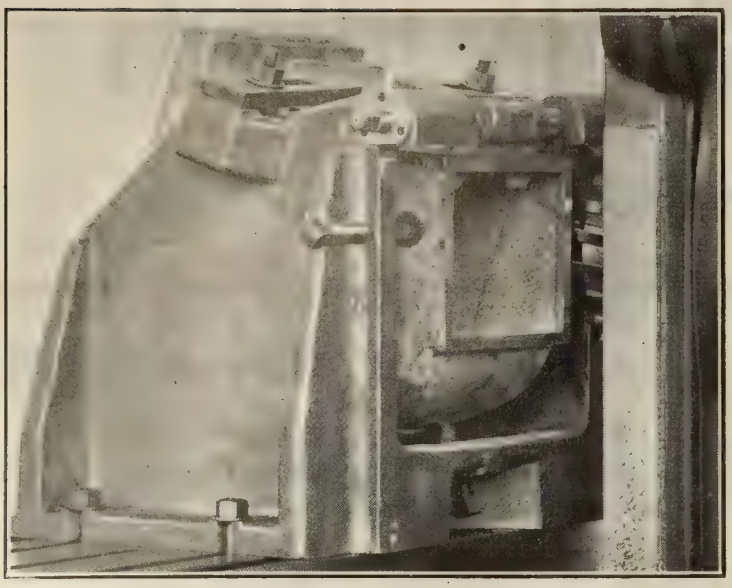

Fig. 1.—Facing large axle box on miller.

home at the weakest spots. Often he will be able to offer a most unlooked for suggestion, so that even should you think that a certain part cannot be machined on the miller, ask him anyhow, and he may surprise you by developing a method whereby you can place the piece on such a machine.

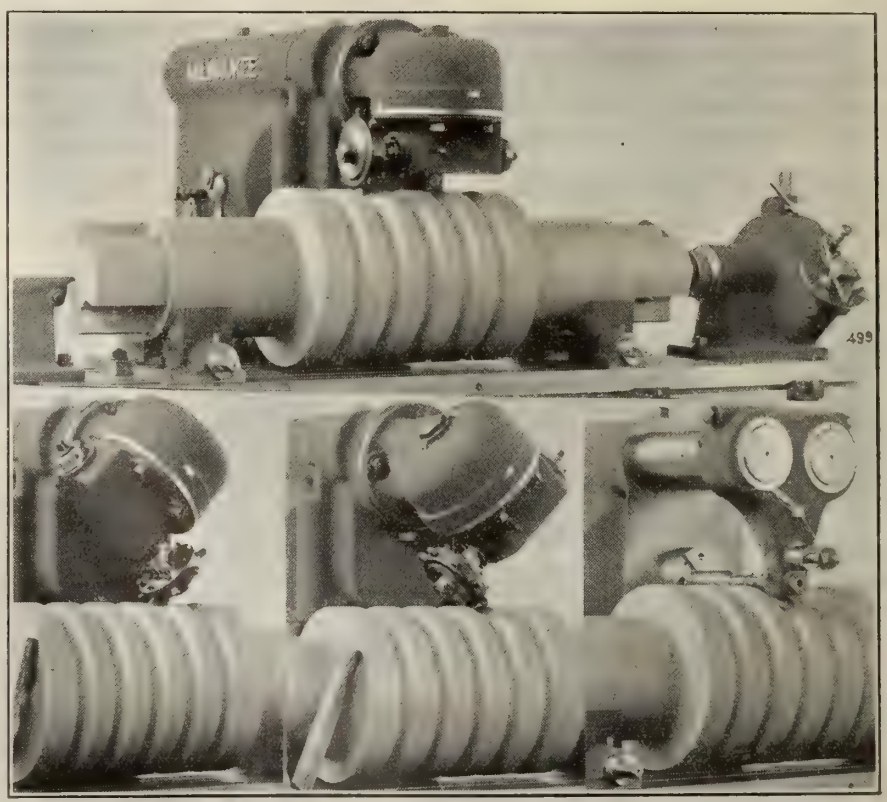
For example, many shops would be inclined to machine the part shown in Fig. 1, on a planer, but the North-Western Malleable Iron Co. felt it could be done on the miller, and proved their contention to be correct. The part shown is a journal box, and the fixture used for holding is both simple and effective. As the picture tells the story we will pass on to Fig. 2, which shows the top and bottom of a table for a special machine being milled.

The value of gang cutters is clearly brought out in this photograph, and it will be noted that the arbor yoke is used as a brace near the point of greatest stress. Where more than one operation of slab milling is performed, right and left hand spiral cutters are generally used to neutralize any end thrust, and it will be noted that this is done in both Figs. 2 and 3. The size of cutters used in Fig. 3 are a little larger than the usual run, and the work being milled calls for a combination of wide slab, and straddle milling.

Milling Notches in Rolls

The next four illustrations Figs. 4, 5, 6 and 7, shows a very interesting job for a milling machine, and emphasizes our former contention that the miller can often be used on work which was thought unsuitable for such a machine. The part shown is known as a chilled roll, and the machine in this case is fitted with a slow speed universal milling attachment. Special adjustable knee grooves are made to support the work. Due to the extreme hardness of these rolls, a cutter speed of one revolution every minute and a half is necessary, as any greater speed than this would soon break down the cutters.

The slow cutter speed is obtained through a set of reducing gears in the universal milling attachment, the spindle of machine revolving at the regular speed shown on speed plates.



The method of supporting the rolls is clearly shown, and it will be noted that these blocks are adjustable. Indexing is obtained through the plain indexing head at the end and the notches on both sides of the feed groove are also cut on this machine. The versatility of the universal milling attachment is well brought out in these views, and the procedure of operation can be easily followed.

In concluding this short article, which shows only a few scattered examples of milling work, we again emphasize the fact that careful planning of jigs, fixtures and cutters is essential if the machine is to deliver its best work. Study your operations. Can they be performed to better advantage on the miller? If so by all means transfer them to such machines, for we are living in an age where efficiency counts.

On the other hand, if you feel the miller is not the proper place for the operation, decide to make a change, but above all make sure you are correct in your deduction. Give the machine a chance to make good. If you feel that it cannot, owing to the work being unsuitable, then take it off and clear the way, so that other parts can be handled, making your milling machines become as efficient as they possibly can.

An important factor to be considered in the successful production of work on Milling Machines, is the careful selection of lubricant for maintaining a keen edge on the cutters and obtaining the desired results on the surfaces being machined. The method of application is likewise a detail that should not be overlooked. It is nearly always advisable to have a good flow, particularly in the case of iron and steel, as this aids the washing away of the chips and presents a clear path for the cutter at all times.

The City of Peterboro, Ont., is having plans prepared for a pumping station. An electrically driven centrifugal pump will probably be installed. The cost will be in the vicinity of $200,000.

Figs. 4-5-6-7.—Showing various roughing and finishing operations on a chilled roll.

Examples of Modern High Speed Production

Methods Adopted At Ford Motor Plant—Mechanically Operated Wrenches Reduce Costs—Machining Countershaft Spool and Cast Iron Axle Housing—Operations on Motor Frame

By H. A. WILSON

PROBABLY more than any other single factor, the development in tool steels during the past twenty years has contributed to the general speeding up of machine shop operations. The greater speed and heavier feed that the steels could handle, was really a heavier burden than many machine tools could take care of. Thus, the design of machine tools became more rugged, distortion, strain and vibration being the influence of the greater capacity minimum. It is for this reason that all types of machine tools have been feeling the influence f the greater capacity of high speed steel. The size of lathe spindles, and the main bearings that carry these spindles, would cause exclamations of surprise from designers who had been out of touch with the industry for the last twenty years. Other factors that have each had their part to play in the drama of "Speedy Production" are, the development of steel for purposes other than tools, better bearing metals, and the increased demand for products which permitted manufacturing on a large production basis. This latter phase called for the development of the screw machine, the semi-automatic, and full-automatic lathe, and all other forms of automatic machinery.

Machines of varied designs have helped to speed up production from the raw material to the finished article. In the foundry, the sand mixers, the moulding machines, pneumatic rammers, air hoists, electric cranes, sand blasts, air chippers, etc., all contribute their share. Punch presses now work up steel sheets in a few seconds, into shapes and forms that were formerly produced in the foundry. Bar stock now enters a factory and later, when fed into screw machines is made into a variety of products very rapidly.

Thus, out of many rapid processes that are almost too numerous to enumerate, a few representative ones have been chosen The mechanical engineering profession has achieved so many wonderful things that it can be truly said that it has had a large part in the moulding of the civilization we enjoy to-day.

High Speed Production

Mr. R Gage, of the Ford Motor Company of Canada, briefly sums up the high speed production activities of the Ford plant at Ford, Ontario, as follows:—"Without attempting to outline all of the many ways and means, by which the company I represent have, by years of study and careful planning, been able to speed up production, the folowing general summary is submitted:—

"There are certain fundamental principles which have been strictly adhered to, and carefully followed out all through the years, which have reduced the number of operations, and have cut overhead cost to a minimum. This has been accomplished by making the machines as nearly automatic as possible, and so positioned as to cut down repeat labor to a very fine point, and second, by installing a system throughout the shop and assembly lines, which practically abolishes confusion and delay.

"The Ford Motor Co. has taken every advantage of modern machinery. Many of the machines used are built expressly for a particular job and carry out many operations in one, all that is required of the operator being to change the part when finished and instal another.

"The large milling machines used to plane off the top of motor blocks holds fifteen pieces at one time. All that is

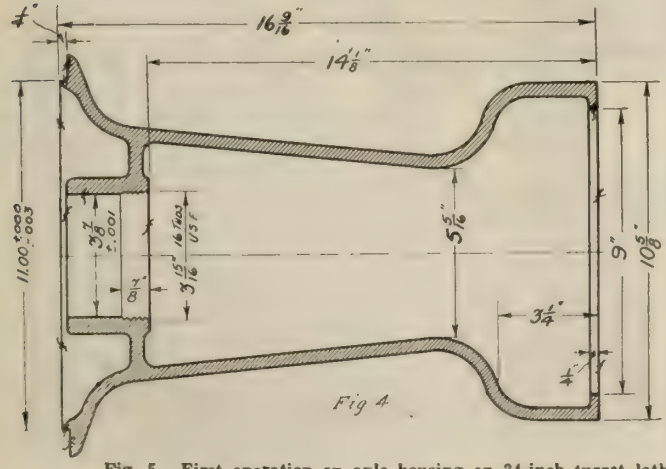

Fig. 5.—First operation on axle housing on 24-inch turret lathe.

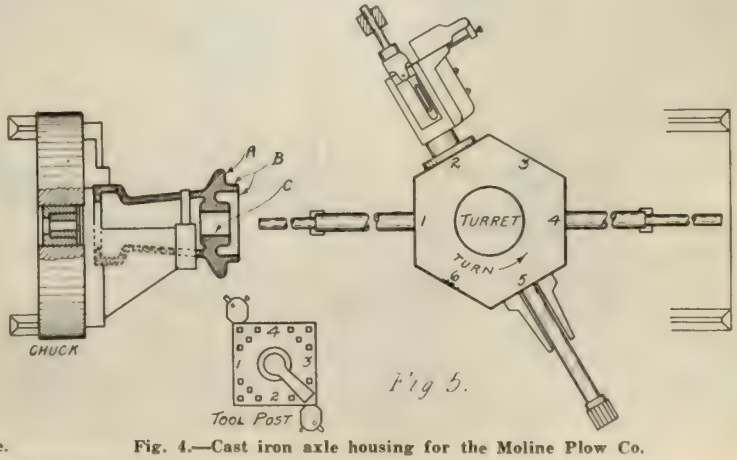

Fig. 4.—Cast iron axle housing for the Moline Plow Co.

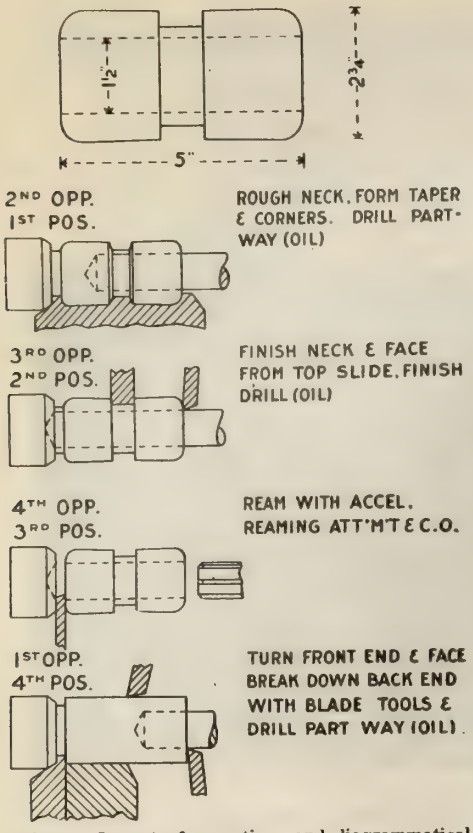

Fig. 3.—Layout of operations and diagrammatical representation of tools used.

required of the two attendants is to position the blocks, start the machine in motion, and take the blocks off as they come through. The machine that drills the holes in the bottom, top and sides of the motor block has 42 drills all operating at once, and when the part is taken from the clamping device, each hole is drilled to its required depth and in its exact place with no confusion, and in one operation. Much time is saved by this one machine alone. If it were not for a tool like the one described, the block would have to be placed on many different machines, or at least located in a number of positions on one machine, which would take much longer and not be nearly as accurate.

Cutting Gear Teeth

"The machine which cuts the teeth in the large differential drive gear is so automatic and reliable that one man can easily operate several at once. On the almost superhuman machines which

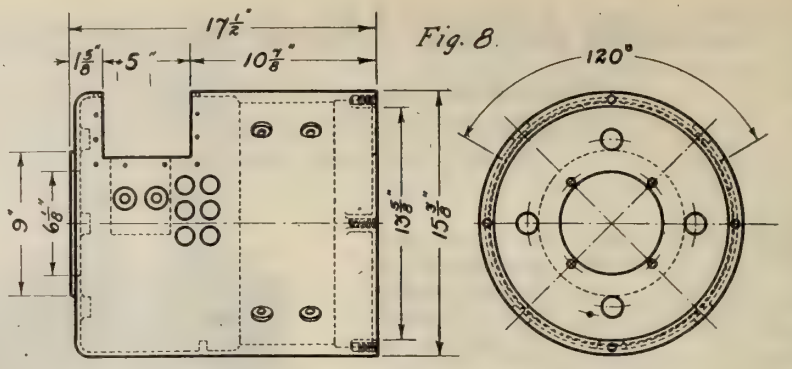

Fig. 8.

Fig. 8.—Cast steel motor frame.

shape and cut the threads on the different bolts used throughout the car, one man easily operates several machines for all he does is to shovel the bolts in a large hopper at the top. Each bolt is automatically fed into the machine and they are turned out, with almost lightning speed. By the use of huge punch presses weighing many tons and exerting a working pressure of 900 tons, the engine crank cases are stamped from cold sheet steel in one operation.

"The system of conveying pieces from one machine to another plays an important part in fast production. Running throughout the shop are huge overhead tracks on which operate electric cranes. These quickly carry parts from machine to machine and to all parts of the yards where needed. Between machines short tracks have been installed on which are small lifting hoists which save exertion and time on the part of the operators. Then again, numerous small electric trucks on which are installed cranes, also raising and lowering platforms wend their way at high speed to all parts of the building, and as they steer from both front and rear they can get into almost inaccessible places to receive or discharge a load. These trucks carry parts from the machine shop to the assembly floors and stockrooms. An efficient elevator system also plays an important part in carrying trucks, etc., to the different floors.

"Perhaps the most impressive and efficient is the motor and final assembly lines. For instance, in the motor assembly line the bare block enters one end, and as each successive operation in turn presents itself, it is taken care of by a workman who is trained to do that particular job. His training consists mostly of being able to do his part in a given time. In a surprisingly short period a complete motor emerges from the other end of the line ready for testing.

"The final assembly is equally efficient. It is composed of a number of assemblies starting with the frame, and as the chassis proceeds down the line smaller assemblies are added until the car is driven to be tested under its own power. The workmen have their own particular parts to assemble and soon become very efficient and speedy in the use of the tools required for that job.

"Wherever it is possible, high speed electric and compressed air speed wrenches are used. These save considerable time over the hand wrench system. Throughout the shop the different operations are made so simple that a new man can be taught an operation within a very short time. On the packing and shipping floors we see the same system employed as throughout the shop and assembly floor. By installing system and machinery, and cutting down the human element in this way, production is considerably increased and the quality of the work turned out improved."

Producing Parts Rapidly

In connection with the production of actual parts at high speed on the automatic screw machine, the following article has been prepared by Mr. G. S. Tracy, of the National Acme Co., Cleveland, Ohio, and illustrates operations on Acme multiple spindle automatic screw machines.

"Producing work at high speed is, of course, a matter of comparison—it is a relative, rather than an absolute, phrase. For instance, what would have been considered high speed 20 or even 10 years ago, is to-day only mediocre. In all probability another 10 or 20 years will bring further important changes in machine tool design tending towards increased production and increased efficiency—higher speed. It is with this in view that these observations are being made.

"We might have chosen a small brass piece and pointed out how we could handle the various operations on our new style 9/16 in. Gridley multiple spindle automatic with such speed that a complete piece from bar stock to the 'tote-box'—was only a matter of 3. 4

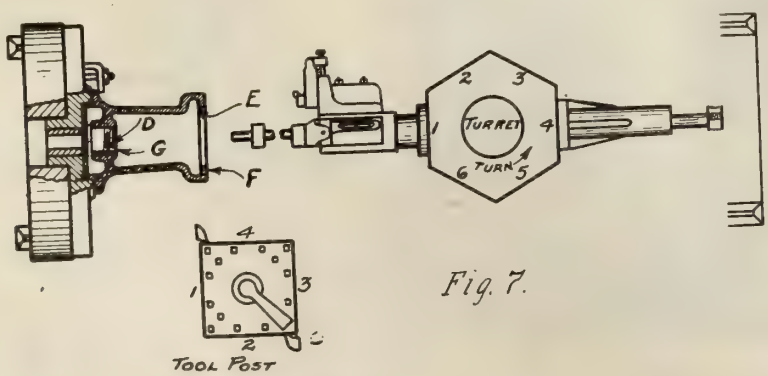

Fig. 7.

Fig. 7.—Second operation on cast iron axle housing.

or 5 seconds as the case might be. We are rather proud of the production attainable on these new style machines, but after all it merely illustrates the application of a speedier type of the same kind of machine that has always handled work of this sort. On the other hand, the part which we have chosen to illustrate brings out the application of a new type of machine to a general class of work whose size has heretofore required the use of a turret lathe or at best of a single spindle automatic.

"The screw machine job shown is a spool supplied on the counter-shaft by a manufacturer of heavy machinery. While the outside diameter of the finished piece is 2¾ in. it might for all practical purposes have been 4 in. For the National Acme Co. now has on the market machines of this type capable of handling round stock up to 4 in. in diameter. The piece is 5 in. long and has a 1½ in. hole drilled through its entire length. It should be borne in mind that since all the tools work at once the time necessary to perform all the operations on any piece cannot exceed the time necessary for the longest single operation or fraction thereof. Hence, much of the idle time usually consumed in the swinging of tools between cuts has been entirely eliminated, and the four indexing positions of the stock carrying cylinder, as well as the movement of tools up to the point of cutting, are all controlled by accelerated cams.

Machining the Spool

The machining operations on this piece shown in Fig. 1 were performed on a 3 in. automatic. As is customary on large machines of this type, the finished piece is cut off in the 3rd position, thus making possible the use of the two lower slides for the heavy turning and drilling operations. This is somewhat different from the usual method of automatic screw machines, but Fig. 2, showing the cut-off side of the Acme Automatic, should give a clear understanding of the general tooling methods employed.

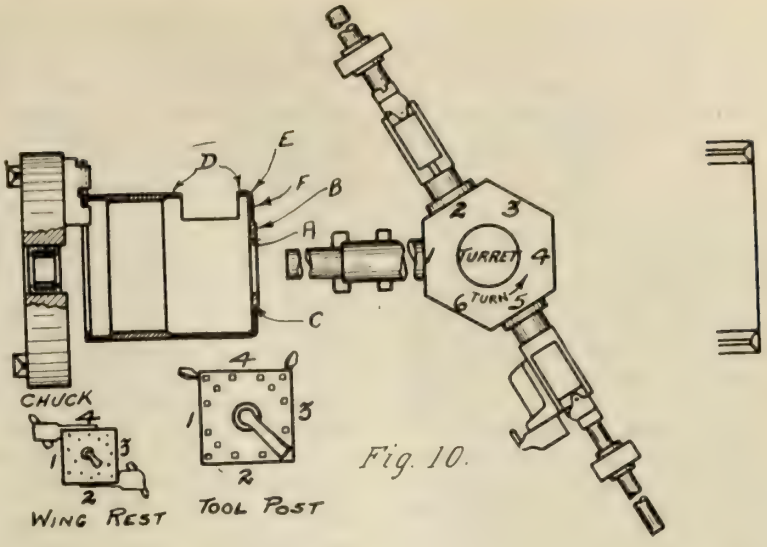

Fig. 10.

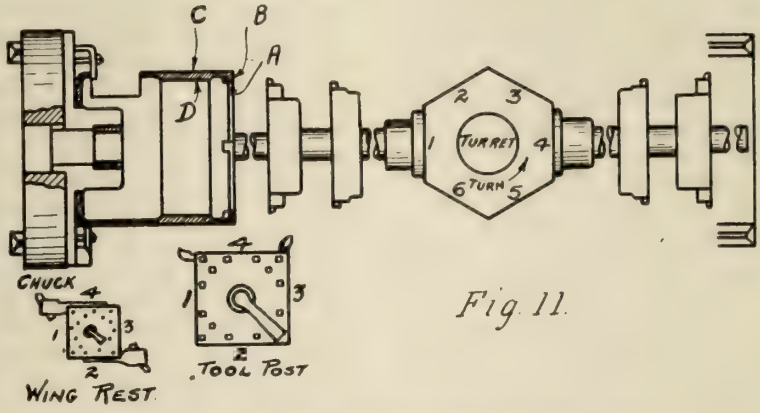

Fig. 11.

Fig. 10.—Tooling layout for first operation on motor frame.
Fig. 11.—Tooling layout for second operation on motor frame.

"The first operation, which is performed in the fourth, or usual cut-off position, is to turn the outside diameter of the stock, face the front end of the spool, break down the back end with blade tools from the cut-off slide and drill part way with an oil drill. All of these operations will be made clearer by a glance at the layout of operations in Fig. 3 which includes a cut showing the tools used at the end of this article.

"We now turn to the so-called forming side of the machine. In the 1st spindle position the 2nd series of operations are performed. These consist of rough necking the groove, forming the corners of the piece, and forming the taper by means of a forming tool mounted on the forming slide. It is necessary to use a forming tool for this work in-

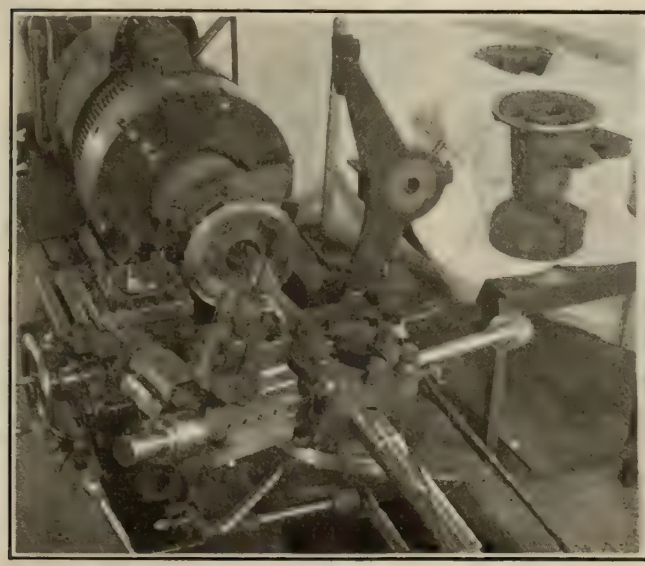

Fig. 6.—Cast iron axle housing in 24-inch turret lathe.

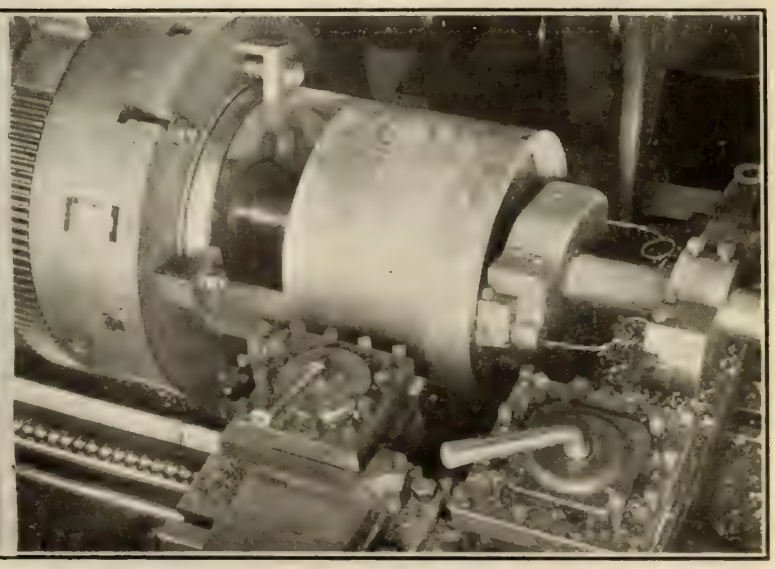

Fig. 9.—Motor frame in a 24-inch turret lathe tooled for second operation.

asmuch as there is a slight taper of the outside diameter of the piece extending from either end towards the groove or neck in the center. In this position the drilling operation is also continued.

"In the second spindle position the groove or neck is completed and the final facing of the outer end also accomplished by the use of tools mounted in one of the top slides. This slide is clearly shown in Fig. 2. Notice that the top slide furnishes extra side tool positions for both the second and third top slide are usually light finishing cuts —just as in the present instance—where a high finish is required for the work. The drilling of the hole is also completed. In the third spindle position the hole is reamed with an accelerated reaming attachment shown in Fig. 2, and the finished piece cut off by a blade tool mounted in the top slide.

"Particular attention is called to the fact that while the drilling operation is split up over three different tooling positions, the whole length of the hole is reamed in one position. This requires the use of an accelerated reaming attachment, shown at left center of Fig. 2. You will notice the long arm of lever, which, actuated by a kicker or dog running free on a stationary rod, gives to the reamer a speed greater than that of the tool slide on which it is mounted. The reamer holder, of course, runs free in the end slide tool holder.

Chute To Carry Away Work

"A point which may be of interest to our readers is the chute for conveying the finished piece away from the tools after the completed piece is cut off. This is shown clearly in the picture of the cut-off side of the machine. In the case of heavy parts of this nature it is desirable to keep the finished pieces from damaging tools or themselves by falling promiscuously.

"The foregoing discussion of the various methods employed on this particular piece should give our readers an idea of how the application of multiple spindle automatic screw machines to a large variety of heavy parts made from bar stock means not only efficient production, but more than that, it means producing at high speed."

High Speed Turret Lathe

We have considered the field of operation of the automatic screw machine and will now turn to some examples of the turret lathe on high speed production. The first article we will discuss is a cast iron axle housing for plow machines. The work on this and the following example is performed on a 24 in. turret lathe. The axle housing is illustrated in Fig. 4. The machining is done in two operations and the total time consumed in the two operations is eleven minutes. The first operation and diagrammatical sketch of the tooling, is shown in Fig. 5. The casting is held in a cradle and special hardened steel jaws which are shown in Fig. 6. The first sub-operation is to rough face surfaces "A" and "B." This operation is done with the tool in side No. 1 of the tool post. The tool post works up to stops, the automatic feed being used. The next detail is to rough bore the internal surface "C." This operation is accomplished by a double blade boring tool in the bar in side No. 1 of the turret. When boring, the bar extends into the chuck where it is steadied in a special casting. The turret is next indexed and the tool in side No. 4 is brought to the work. This double blade boring tool finish bores the interior surface "C." Next the turret is swung around and the reamer in side No. 4 is used to ream "C" to size. The last turret sub-operation takes place when the tools in the head mounted on the bar projecting from side No. 2, are used to finish the surface "B." A roller guide in "C" is used to steady the operation, and suitable stops are provided to insure uniformity of the operation. The final detail operation is the finishing of the surface "A" by the tool in the side No. 3 of the tool post.

In the second and last operation on the axle housing it is turned "end for end" when clamped to the chuck plate with specially bent straps. The diagrammatical layout of this operation is shown in Fig. 7. Surface "F" is rough faced with the tool in side No. 1 of the tool post. Next "E" is bored and chamfered with cutters in the head, and bar mounted on side No. 1 of the turret. The following sub-operation is the finish facing of "F" by the tool in side No. 3 of the tool post. To give proper length to the casting the tool post is placed against a stop which accurately determines the finished length of the axle housing. The final detail is the tapping of "D" with the tap in the side No. 4 of the turret. This completes the machining of the casting and after carefully studying the dimensions shown in Fig. 44 it is really remarkable that these operations can be completed, including two set ups, in the short period of eleven minutes.

Machining Motor Frame

The next example of turret lathe work is the machining in two operations of a motor frame of cast steel for the Cleveland Armature Works. This work was also done on a 24 in. turret lathe. The piece is shown in Fig. 8. The piece set up in the lathe is shown in Fig. 9. A diagrammatical layout of the tooling for the first operation is shown in Fig. 10. The frame is chucked in special hard jaws. The first sub-operation is to rough face surfaces "B", "C", "E" and "F" with the tool shown in side No. 4 of the tool post. Next the surface "D" is turned with the tool in the tool holder of side No. 1 of the turret. Following this the surfaces "B" and "C" are rough faced with cutters in the head on the bar in side No. 2 of the turret. Then "F" is finished with the tool inside No. 3 of the tool post. The surfaces "B", "C" and "E" are finished with cutters in the head and bar on the side No. 5 of the turret. It will be noted that a double support is used to steady the bar, one in the bushing in the chuck and the other with a roller in "A." This prevents distortion and the consequent inaccurate work. The last detail in the first operation is to finish "D" with tool in the holder on side No. 2 of the wing rest. The total operation is completed in 57 minutes. The second operation requires that the motor frame be chucked "end for end," shown in Fig. 11. It is held firmly on the chuck plate by clamps, after being centered. The surface "B" is rough faced with the tool in side No. 4 of the tool post. Next the surface "C" is rough turned with the tool in the holder on side No. 4 of the wing rest. Following this the surfaces "A" and "D" are rough bored with cutters in the boring heads carried on the bar on side No. 1 of the turret. The finish boring of these surfaces immediately follows, with tools carried in the boring heads on the bar on side No. 4 of the turret. The next sub-operation is to finish face "B" with the tool in side No. 3 of the tool post. The final detail in the second operation is to finish turn "C" with the tool in the holder on side No. 2 of the wing rest. This second operation is completed in 60 minutes. Thus the total machining time of the motor frame is 117 minutes, which is a remarkable achievement.

With these few examples we are forced to close the article feeling that the examples of high-speed production in the shop are "legion."

AVOIDING CRACKS IN CASTINGS

Speaking on "Cracks in Aluminum Alloy Castings," Mr. R. J. Anderson of Pittsburgh, Pa., in the course of a paper, says that the melting temperatures should be low; overheating in the furnace should be avoided. Open-flame furnaces should be run with a non-oxidising atmosphere in order to avoid the formation of much aluminum oxide, and consequently occluded dross in the alloy. Skimming should be adequately and carefully done and the melting practice should be conducted as cleanly as possible. Foundry floor sweepings should not be charged into the furnaces unless sieved and foreign materials should be kept out of the furnace charges. The pouring temperatures should be as low as is consistent with filling the mould readily with metal; high pouring temperatures should be avoided.

Damage to the extent of about $250,000 was caused by a fire this week in Montreal when a moving picture theatre, the premises of the National Stove Manufacturing Co., and a number of dwellings were destroyed. Defective wiring is supposed to have caused the fire.

The Leonard Medal, given for the best annual paper presented before the Engineering Institute of Canada of the Canadian Institute of Mining, was presented recently to Col. R. W. Leonard. The medal is in the shape of an irregular moulding, resembling a nugget, smoothed out, and is worth intrinsically about $60. It might be stated that the medal was made from the product of Col. Leonard's own mine, the Coniagas.

How to Reduce Manufacturing Costs

Heads of Various Organizations Tell How They Have Managed to Cut Production Costs—This Story of What Others Are Doing May Enable You to Solve Your Own Problems

THE BUSINESS man's chief problem at the present time is to reduce the cost of producing his merchandise and so be able to offer it at a price which will induce his customers to buy. Various methods have been given by production managers as effective ways of lowering production costs, among which are:—"Greater production per man," "Reducing the varieties of products," "Solving Transportation difficulties," etc.

In Forbes, Alexander A. Field relates how he has asked the heads of several organizations what methods they have found most successful and he gives their replies.

"Perhaps no better example of the solving of the common problems of the smaller plants can be offered," says Mr. Field, "than the system in use at Bush Terminal, in Brooklyn. Not only may the manufacturer rent his space foot by foot, as he needs it, but he may also secure metered power, light, extra service, warehousing by the foot, trucking by the hour, the use of cars which are handled on the company's own switch yards and which are run up beside his own loading platforms, stevedore service, and many other conveniences usually out of reach of the small manufacturer.

Keeps Workers Satisfied

"Robert R. Gerstner, vice-president of the Oil Products Company and president of the Merchants' and Manufacturers' Association of Bush Terminal, said:

"'One of the great factors in production costs to-day is the enormous labor turnover. Manufacturers are making a constant effort to eliminate from their ranks the 'floater,' the employee who looks for another job during the lunch-hour.

"That a partial solution of the labor problem in production will come with the 48-hour week, divided up into five days' work, is the opinion of Henry Nias, president of the Public Service Cup Company, who has tried it out very successfully in his plant.

"'Efficient help, properly trained,' said Mr. Nias, 'will deliver as much—if not more—production in a 48-hour week, proportioned at 9½ hours' work a day, as they will in 52½ hours, working six days. Saturday is a broken day anyway, if worked as a half-day and efficiency is low. I believe that if our workers have all day Saturday and Sunday they will do better and more rapid work, they will be happier and more contented and their production will increase. Rapid work with more production per man or woman lowers costs all the way down the line—lights, power, supervision, office costs, wear and tear on machinery, etc.

"'We have a rigid plan of maintaining the highest grade of help. There is no shifting of responsibility, no dragging. Each section of our operating floor is under supervision. When we train new girls, we select them for speed and efficiency and the machine they use is geared to an exact setting for their speed. As their speed increases we reset the machine. The operator then keeps up to the speed set by the machine she is using, and her output is steady and even.

Maintenance of Raw Materials

"'A great cost reducing system is the careful stacking and placing of our raw material; so that we always have a standing inventory. I can tell very quickly whether it is wise to buy or not because in five minutes I can have an exact statement of what we have on hand. The maintenance of raw materials in an accessible and orderly condition is a vital cost reducer to any manufacturer, not only because it eliminates waste, but also because it prevents careless buying. Immediate knowledge of his stock enables a man to take quick advantage of a lowered market or to 'stand pat' on one that is going up, if he is properly supplied. Since we know exactly how long a certain amount of stock will last us under normal conditions, with an inventory right at hand, we cannot make a very serious mistake.

"'Because we are subject to seasonal demands, due to our large business with drug stores and ice cream parlors, we have found it desirable to have all our machinery installed in exact duplication on the two floors of our plant. We can now shut off one floor entirely when production is low.'

"'We have found several systems effective in reducing our production costs,' said J. K. Zitz, treasurer of the Agar Manufacturing Corporation, manufacturers of corrugated cartons.

"'By inaugurating a bonus system based on the production of each man, we have materially increased our production per man. The bonus is based on an estimate of the worker's normal output for a given period. Anything over normal production is subject to a bonus. If a man running a machine has one or two helpers, all share in the bonus in proper proportion to their work. Our labor turnover has very materially decreased since this system was installed, and our production has been greatly increased.

"'Another thing that keeps costs down is our system. Once a month we meet to discuss our budget and to make comparisons of previous costs. We use the utmost care to keep our machinery up-to-date, replacing it wherever necessary.'

Labor Turnover

"Inspection of other plants revealed many economies which might be generally adopted. If every factory could successfully concentrate on higher production per man; reduction of labor turnover; decreasing the varieties of the product; and the elimination of waste by better methods, salvage, and the utilization of by-products, said a production manager, there is no doubt they would find an enormous decrease in their production cost per unit. Every worker should be encouraged to produce to his full capacity, by offering proper labor conditions, a well cooked mid-day meal at the plant, co-operative stores where wholesome food can be bought at a minimum, proper labor-saving machinery kept at the highest point of efficiency, and added inducements in the shape of a bonus or some profit-sharing system.

"The question of labor turnover is gradually adjusting itself as business swings back to normal. But few organizations have even been able to boast of the three-generation labor conditions which have made the Henry Disston plant famous. Such methods as those used by the Studebaker Corporation where employees receive a bonus in proportion to their length of service, have, however, proved satisfactory. Other plants have reduced their labor turnover by the creation of goodwill and a family spirit among their people. Far-famed for this spirit is the Endicott-Johnson Shoe Company, whose employees have a Spotless Town of their own. Many other instances might be cited where the manufacturer has so considered the personal interests of his people that he has bound them together more as a family than as an organization. In such plants labor turnover is a negligible quantity.

"Efforts to reduce the varieties of the products manufactured have opened the eyes of executives to many things heretofore unknown. One manufacturer discovered in analyzing his output that 75 per cent. of his business was centred on a few items. He hesitated to concentrate on these few, fearing that by diminishing his line he would reduce his sales; but after testing the matter out he discovered that he could so reduce his cost of manufacture by specializing on these

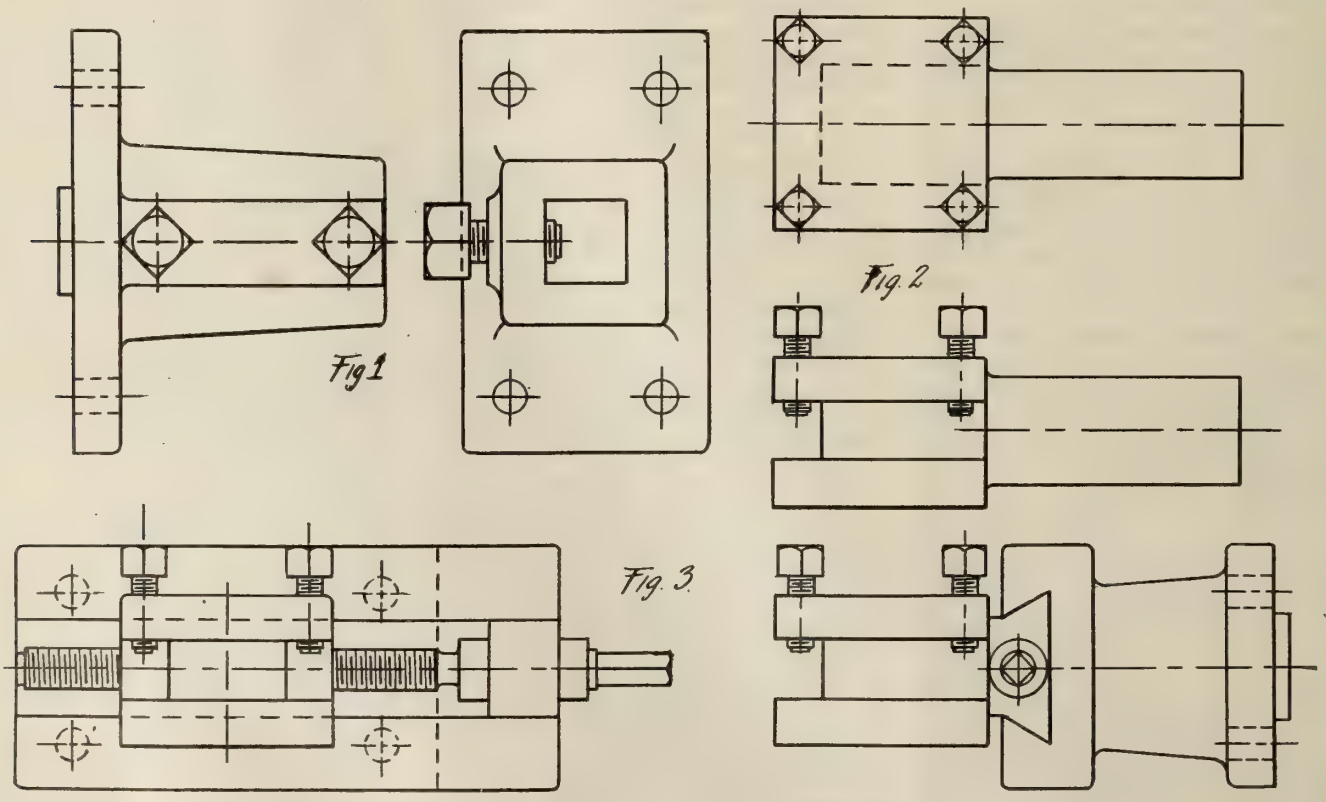
(Continued on page 43)

Developing Turret Lathe Toolholders

Method of Holding Cutting Tools—Showing Improvements In Design—Advantages of Modern Type—Adjustment Facilitates Tool Setting

By HUBERT BENTLEY, A.M.I., Mech.E.

THE efficiency of a lathe is largely governed by its tool and toolholder. However powerful the driving headstock may be, the results attained can be largely nullified by the cutting tool employed or the method of securing the same. While these remarks have general application, they apply with considerable force to the hexagon turret lathe, on which type of machine it is quite easy to spend a considerable sum in tool equipment. During recent years a considerable number of lathes have been built, more or less standard engine lathes but fitted with hexagon turrets in place of the ordinary slide rests and minus the loose headstocks. These lathes can be employed quite satisfactorily in works where the quantities of repetition work are not sufficient to warrant the introduction of the more expensive modern capstan and turret lathe.



Many of these machines were built for war time service and are now available for other work, and works managers are frequently called upon to utilize one of these tools when probably a standard engine lathe would be more suitable. In the type of lathe where the hexagon turret is fixed permanently in regards to cross traverse, the necessity will soon arise for some degree of tool adjustment, if facing operations have to be made on the work being chucked. Where the turret has a cross traverse motion the difficulties of having to continually set and reset the turret in its different positions after each operation also make it advisable to provide independent tool adjustment.

Fig. I represent the simplest form of toolholder. This is secured to one of the turret faces by four screws and in the best practice also dowelled. The tool used in this case may be of the ordinary lathe form held in place by two hardened steel square head screws. In the fixed turret lathe the tool itself would be set-up in the holder to give the required bore. Fig. 2 is a development on Fig. 1 in so far, that three tool positions are provided in one tool holder. If the left hand tool is reversed two tools can be in operation at the same time. The round shank of this holder fits the hole bored in the hexagon turret face.

Difficulties occur with this type through lack of adjustment as in Fig. 1 and eventually from these two was developed the toolholder shown in Fig. 3. This provides a simple screw and nut adjustment to the tool holder which not only facilitates tool setting, but also enables facing operations to be carried out by hand independent of the turret. A preliminary cut taken across the face of a wheel boss or similar job to remove the black will extend considerably the life of the boring cutters that follow.

The steel toolholder itself provides three positions for the tool and it is machined to the desired shape from the round bar. The inner end is vee-shaped and is carefully fitted to the planed vee-ways of the toolholder casting which is screwed up and spigoted to the turret face. A square thread screwed is mounted in this casting and engages with a nut cut in the toolholder and by this means the holder may be traversed from end to end of the slide. To facilitate planning, the bearing for the screw is made separate and firmly secured by pins. Suitable collars take the end thrust while the end of the screw is squared to fit a spanner or handle as desired. It will be noticed that the front end is extended to increase the amount of traverse.

In each case the tools are secured by two hardened steel screws. It might be stated that the toolholders shown were all employed on a 20 ins. swing surfacing and turret lathe, the size of the turret faces being 7 ins. by 4 ins., and the tool steel employed was high speed, ½ in. square section. The design of toolholders grows with experience as shown by the elaborate equipment of the modern turret lathe.

Illustrating development of turret lathe toolholders.

Manufacturing Cylindrical Machine Brushes

Saving Metal From Soldered Joints—Design of Brush Body—Proper Securing of Bristles Essential to Long Life—Rebuilding Brush Bodies—Opportunities For Small Repair Shops

By DONALD A. HAMPSON

THE MANUFACTURER of tin cans has assumed such proportions that, besides the immense plants of specialists, hundreds of consumers operate their own can making departments. Automatic machinery has reduced can manufacture to a science. After leaving the presses, only one or two attendants are required to watch the long lines of parts being rapidly formed and assembled down to the point where workmen remove the newly made cans, tested and cleansed, from the conveyor, and place them in storage.

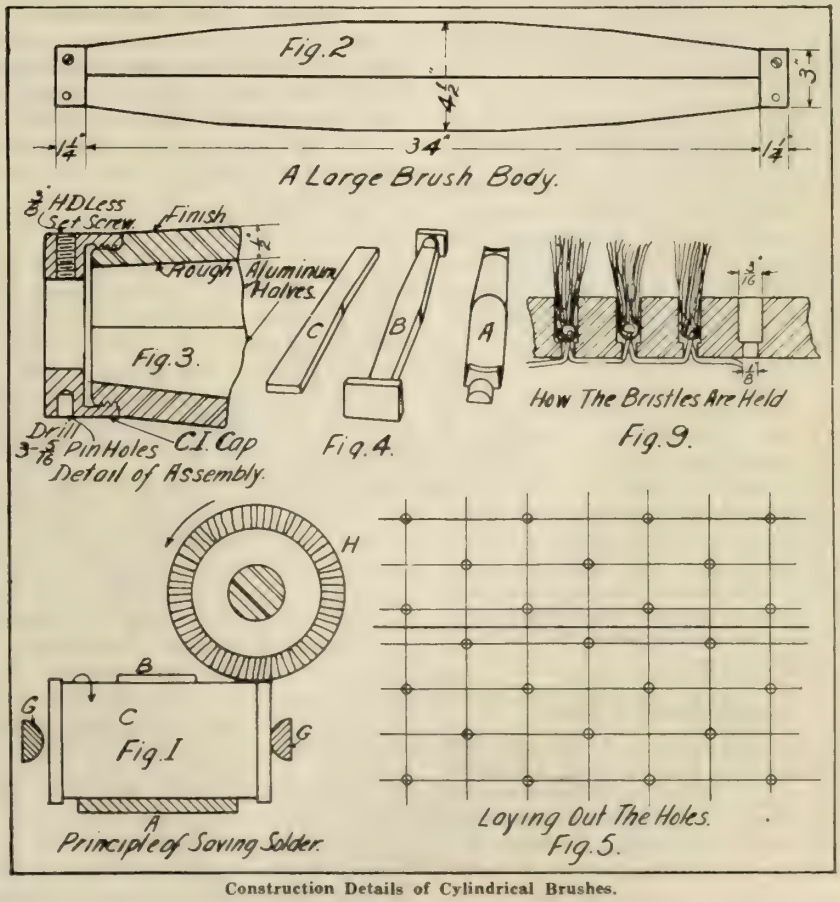
Cans intended to hold liquids are soldered at the joints. Solder, therefore, is one of the big items of expense in the manufacture of this class of cans and any means by which even the fraction of an ounce may be saved on each can results in a considerable reduction in the cost per year. Solder-saving machines have become a recognized unit in the "assembly line."

Operating Principle

Fig. 1 shows the principle of solder-saving machine operation. Here, "C" is the can which, on entering the machine, is caused to roll along the runway "A" by the belt "B" traveling in the same direction and so controlled that it exerts sufficient driving pressure on the entire row of cans in the machine. Two guides "G" position the can, as well as prevent skewing.

During passage of the can through the machine, it rolls in contact with the cylindrical brush "H." This brush may be any length from 18 inches up and it is geared to revolve at a high rate. The length of the brush insures contact twice around the can, or more, and contact with thousands of bristles in the process. The position of the solder-saving machine is close to the delivery end of the soldering machine so that the solder on the joints has not had time to set—it is still hot and soft—and in this state practically all the solder that hasn't penetrated the joint may be removed by the brush.

Selection of Bristles



The making of cylindrical brushes for this particular service has been a rather closely guarded business. Using the term "bristles" to cover whatever material goes into filling the brush, the three requisites of a good brush are—long wearing life, resistance to burning, and bristles with a maximum of springiness. Of these, resistance to burning is hardest to obtain and most brushes are found burned off toward the starting and long before the majority of the bristles are worn down too short. A brush with either animal (bristles) or vegetable (fiber) filler will answer for ordinary brushing purposes, but will not do for the exacting solder work because animal bristles alone soon glaze over with bits of soft solder, while fiber burns away under the heat and is too weak to throw as heavy material as solder. It is not unusual for a brush maker to proportion his stock and experiment for several years, drawing largely from Asiatic markets, before obtaining a successful mixture but when he finds this latter, he is assured of a profitable re-fill business for years to come.

Running on the average 500 r.p.m., a cylindrical brush will last about one month in continuous ten hour operation. Then they are returned to the brush maker to be re-filled, but the cost of this is made up in less than two weeks by the amount of solder saved. In fact, the saving is so large that most plants save the cost of the entire machine in less than a year and the cost of a new brush body (when needed) in a month. The brush body and re-filling charges are quite high and many attempts to remove the superfluous solder by other means have been made; the most successful have been the belt removers but these have often failed because they did not have the "snap," or spring found in bristles and so necessary to prevent glazing and to throw the solder free.

Rebuilding Brush Bodies

Large numbers of brush bodies are overhauled and made over every year, work often being sent long distances to someone who has done it before when local shops could handle it fully as well if they went after it. In these times when business is scarce, contract shops would do well to solicit brush body work from some can plant in their vicinity, starting in this way where there is a community of interest and later reaching out, acquiring thereby a trade which is steady and profitable year after year, even though the amount of business is not large.

Fig. 2 shows a typical brush body of the larger size. The body proper is made of aluminum to avoid the stress-

Construction Details of Cylindrical Brushes.

es set up by heavier material revolving at a rapid rate; it is made hollow, in two halves divided longitudinally, and joined at the ends by cast iron caps, as shown by the section in Fig. 3. These caps have reamed holes to fit the brush shaft and after the body halves are so joined, the exterior of the body is turned concentric with the shaft.

The brushes here shown are larger than the average—smaller brushes are reduced in proportion. Sometimes the exterior is turned straight but more often it is crowned as shown, either in a true arc or, preferably, by turning a flat in the middle and a double taper each side of this, made by two settings of the lathe. Aside from accidents, brush bodies have to be renewed following failure of the threaded ends and when some casting imperfection, coupled with the wear of renewal, make it no longer possible to retain the inserts.

Making New Bodies

The pattern cost for a new size of bodies may be excessive unless carefully planned. Unless a large number of castings are made, it is cheaper to form the halves by use of a dry sand core than to go to the expense of a shell pattern. The patterns shown in Fig. 4 illustrate this point—they were made up for the 34 inch brushes shown in Fig. 2. Here, A is the semicircular pattern, including the core prints. It will be noted that pieces are cast at each end—these are bearing pieces when the casting is set up for milling the center flats; by their use it is possible to have the casting rest solidly at each end and bear at the crown in the center, making an easy set up and preventing inaccuracy through distortion.

The core is swept up by means of B and C which are shaped to the inside contour and include the prints. The runner in B is built up and of sufficient depth to insure its remaining straight. Such a pattern outfit is comparatively inexpensive and answers every purpose.

After the halves and caps are assembled and turned, the holes must be laid out. This operation may be reduced somewhat but when there are several brushes and each with a thousand or more holes, it still remains quite a task. Fig. 5 shows the typical layout. It shows the spacing as laid out in both directions and how the holes are prick punched in staggered order from the lines. At the middle joint, the adjacent rows are slightly closer, for experience has shown that, commercially, there is apt to be a light spot there, noticeable even when this is done to a slight degree.

Laying Out The Work

The simplest method of laying out the longitudinal lines is on a planer or surface plate, using index centers and marking with a surface gauge. For the circumferential lines, the body on a mandrel in the lathe and a sharp pointed tool form the natural method but instead of spacing off the divisions first with dividers, one shop conceived the two-man method in connection with the carriage feed. The operator feeds in the tool at the word from the index man, who sits at the end of the lathe and turns a gear on the feed rod or lead screw a predetermined number of turns which give the desired spacing. The lathe is running all the time but the feed is disconnected. Three-quarters of the old time is thus saved in marking the rings and a more accurate layout is secured.

An automatic (hammerless) prick punch is used to mark the holes for drilling. A girl operator will punch the brush body in Fig. 2 in about an hour; some idea of the task and of the layout may be gained from the number of lines—28 one way and 67 the other. With a crowned brush, the holes near the ends run much closer together; this is the governing factor in the spacing. To build a brush of uniform density, the brush maker puts fewer bristles in the holes toward the ends—this is a simpler method than a spacing which would give uniform density with an equal quantity of bristles making up each insert.

It might be argued that laying out could be avoided entirely by drilling the holes in a milling machine, as indexed. But it is seldom possible to speed the miller to an efficient rate for small holes in aluminum, even if advisable; then, the means of feeding the work on the miller are not nearly as fast as the rack and pinion.

Drilling Holes for Bristles

Simple fixtures of wood are used for drilling brush bodies on a friction drill. More permanent fixtures would be similar but in metal. The mandrel is laid in two vee blocks which are tied together at a distance to just receive the brush and caps. This assembly may be slid lengthwise in a channel formed by a 2 inch by 4 inch piece of maple with sides and bolted to the drill press table so the center lines are coincident. Two drillings are necessary—for hole and counterbore. The best kind of depth gauge for the latter, it has been found, is a piece of wood surrounding the drill this gauges all holes to a uniform depth from the outside regardless of the body contour.

Following the drilling, burrs are removed and the bodies sent to the brush maker. The method of securing the bristles is shown at Fig. 9. It is the same as found on all first-class brushes regardless of shape and has remained practically unchanged throughout the history of brush manufacture. Brass wire is used to tie the bristles—a loop is pushed through from the inside of the body, a bristle insert slipped half way through the loop, and the latter drawn taut. This wire passes throughout the line and back again. As a row is filled, it is trimmed off to the proper height from the body by bench shears fitted with a gauge for the purpose; on solder saving brushes, this height averages 1 inch.

Assuring Firm Bristles

An interesting point in brush manufacture is the means for removing loose bristles. After the brush is filled and the wires tied, the inside is flushed with plaster of paris. Then with caps screwed home, the workman takes the brush to a lathe where an ordinary cylindrical brush on a wood body is revolving at a high rate. Applying the new brush to the one in the lathe, turning it and moving so all parts are brought in contact, effectually pulls out and discards all bristles that will come out. The customer is thus assured that his brush will remain "full" throughout its life and that this solder when collected will be free from foreign matter.

Solder saving brushes represent the most elaborate form of machine brush. There are many other uses for cylindrical brushes, so that practice in this exacting field may serve as a guide for designers and mechanics who may come in contact with them in other fields. Principles are the same but less expensive construction is usually followed.

Cylindrical brushes are used to advantage for cleaning brushes in automatic machines, for feeding or placing sheets of paper or magazines in presses and folders, for polishing, and for a great variety of experimental work. The printing and allied trades are large users of cylindrical brushes. Where brushes handle liquids or paste, metal bodies must be employed and these are constructed along the lines just detailed. In other cases, the half bodies are made without caps but with a chamber throughout all but the short ends, which latter are finished to fit the shaft and then the two halves are screwed the shaft instead of to each other.

Various Types of Brush Bodies

For some work, the cheapest way is to use a piece of tubing, divided longitudinally, and having bushings in each end; four counterbored screws passing through the bushings fasten the brush to the shaft. But for average machine work, the brush body must have a relatively thick wall, otherwise there will not be bearing enough for the insert when under pressure to form a "strong" brush.

Wood brushes appeal to the buyer of experimental work because of their lower first cost and the possibility that the brush in its present form will not be ultimately used. Wood brush bodies should be made of maple or birch; there is nothing gained by using poor wood even for a temporary brush. The chambered inside is retained in the wood brush though for a brush of small diameter wire grooves may be cut with the point of a knife.

Some wood brushes are constructed with an extended body at one end. This extension is grasped in a socket or chuck at the end of the machine spindle.

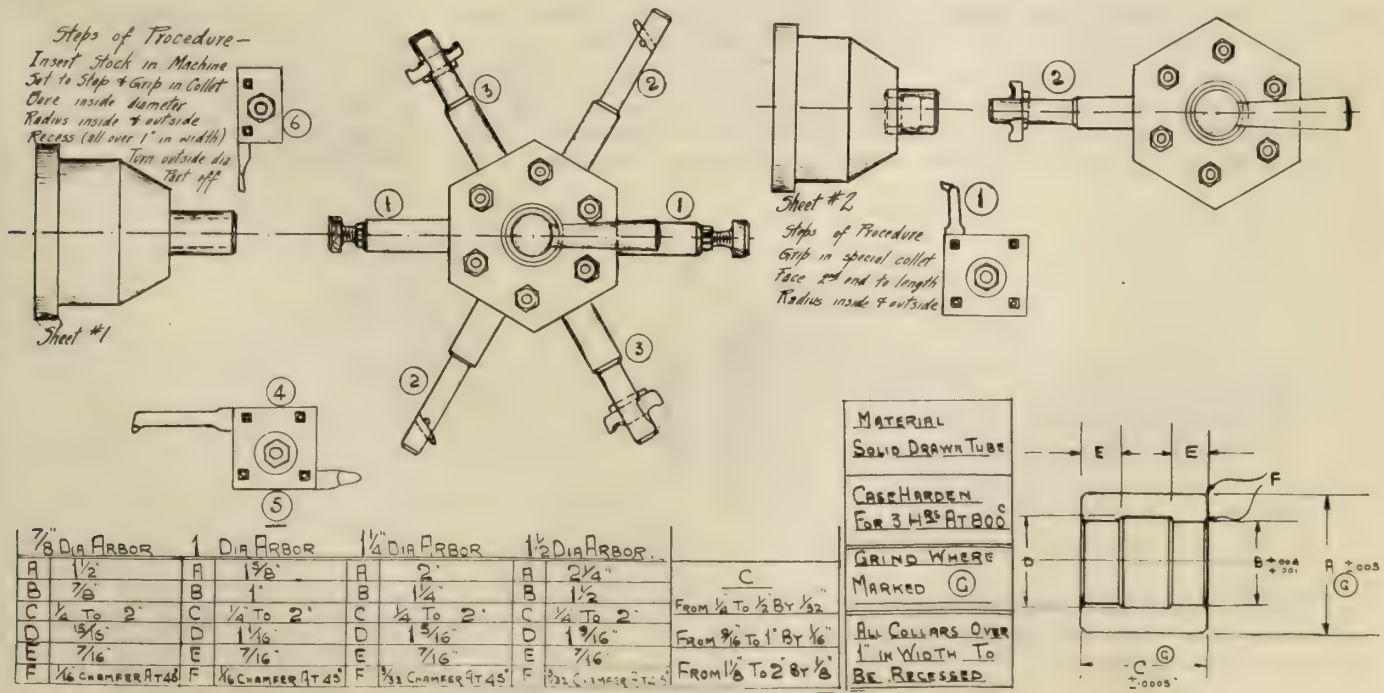
Manufacturing Spacing Collars for Millers

Commercial Production—Disadvantage of Cast Iron for Collars —Danger of Breakage—Various Methods of Manufacture Considered—Selection of Material—Some Production Figures

By G. BLAKE

MANY OF the spacing collars supplied with milling machines are only cast iron, others are of mild steel left soft, and a few are case hardened and ground to size. The subject of this shop article is the manufacture of last-mentioned type on a commercial basis. The fault of cast iron collars is that they are liable to get burred up at the edges and even broken if accidentally dropped. They also get loaded up wtih small chips on the working faces and so ultimately bend the arbor out of truth. The fault of the soft collars is pretty much the same as that of the cast iron ones, omitting the danger of breakage, but accentuating the capacity for loading up with small chips on the working faces and thus bending the arbor.

Generally speaking, the job of making extra collars is relegated to the toolroom—a costly job these days. The methods employed there would in most cases be on the lines here below, viz., cutting the material to length (rough), chucking in 3-jaw chuck, centreing, drilling, boring, turning outside diameter, facing, recessing, radiusing the edges inside and outside and parting off, gripping in 3-jaw chuck, facing second end to length plus grinding allowance. For example, a spacing collar 1¼ in. long for 1 in. diameter arbor would take at least an hour, exclusive of overhead charges. Then the casehardening and grinding would also come out expensive, as toolroom costs are very high for both these items.



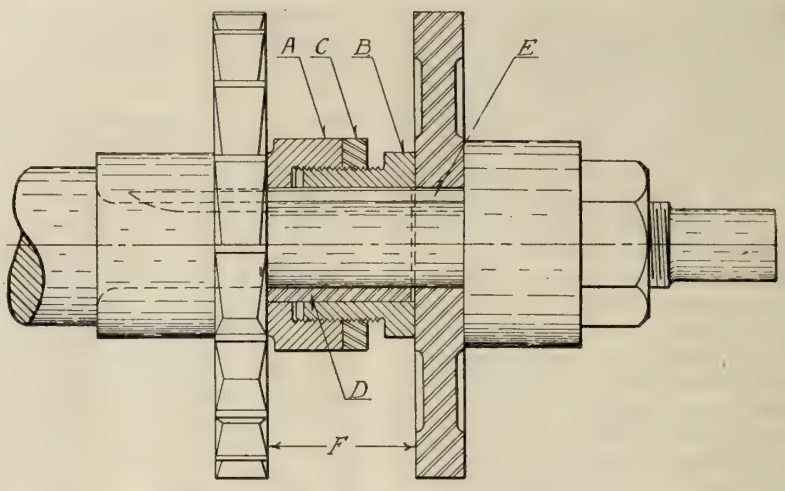
Now let us consider the methods employed in the manufacture of these collars. First of all material used is bright drawn tubing, the bore of which is practically size, requiring only a slight skim with the boring tool. The outside diameter also, being about size, requires only a skim over with the turning tool in the tool post on the cross slide. A capstan lathe is used for thi job. The layout sheets Nos. 1 and 2 show the method of procedure. The master schedule covering the whole series of operations clearly furnishes all information from the raw material to the finished article. As will be noted in layout No. 1 all idle movements are cut out by having two sets of tools in the capstan head. The rate of production for the 1st operation is 12 per hour for collars with recesses; for collars without recesses 20 per hour; for the 2nd operation 30 per hour. 3rd operation, stamping size on each collar, 48 per hour. 4th operation carbonize in batches of 50 in two boxes for 3 hours: 5th operation grinding diameter to size plus and minus .005 in. and length to size plus and minus .0005 in. 9 per hour. 6th operation: gauging bore, outside diameter and length: 120 per hour. The total cost, excluding overhead charges and material, works out at 11 cents per collar approx.

USE AND CONSTRUCTION OF CYLINDRICAL MACHINE BRUSHES

(Continued from page 34)

Generally, brushes of this type are for lighter service where it is possible to dispense with the counterbored, hole and wire method of fastening. This makes a simpler construction, for the body is then a solid round bar or, in some cases, the wooden body is made up of two halves screwed together. Non-hollow wooden brushes are drilled with a plain hole; the brush maker inserts a filling of half length straight in these holes and sets them in melted resin.

Mr. C. J. Smith, manager and secretary of the Montreal Warehousing Company, a subsidiary of the Grand Trunk Railway Co., has stated that his firm is calling for tenders to increase the capacity of the Grand Trunk elevator "B" at Windmill Point. The proposed additions, alterations and improvements will consist of an annex for storage of a million bushels, which will bring the total storage capacity of the elevator up to three million bushels. It is also the intention to install a car-dumping machine for unloading cars, as the present method of unloading by air shovels is not all that is to be desired. A second carrier is also to be built for delivering grain to ocean vessels. The project is to be rushed so that it will be ready for the opening of navigation.



Tooling layout and data making spacing collars.

Practical Ideas from Practical Men

ADJUSTABLE DISTANCE COLLAR

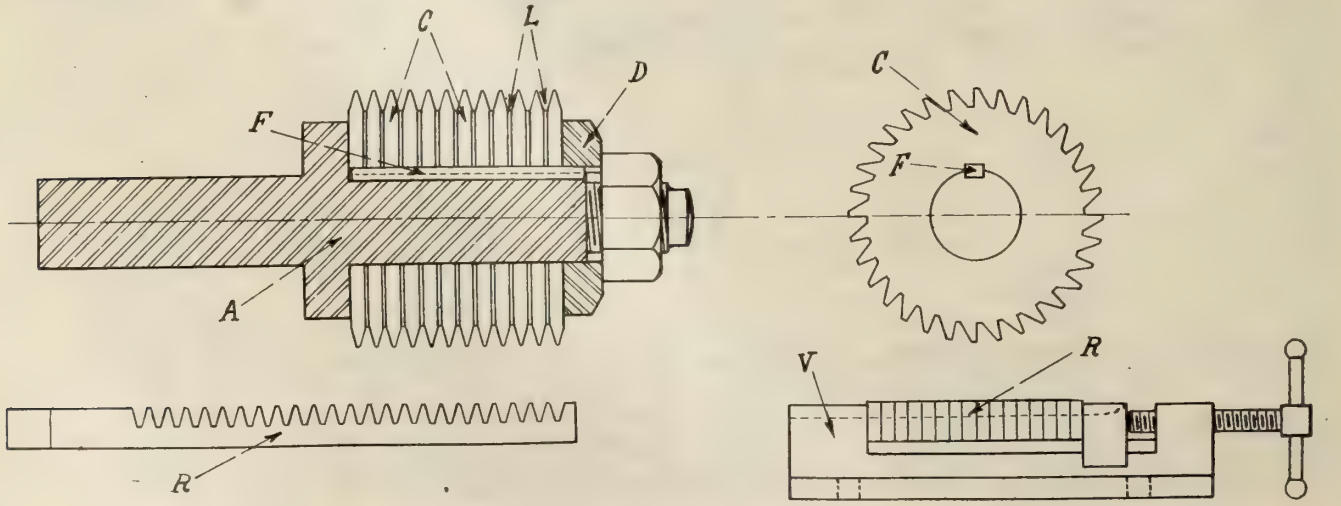
The accompaning sketch illustrates a simple but effective way of adjusting side or face milling cutter to set dimensions. The regrinding of cutters naturally alter the diameter and width of face slightly, and where two or more cutters are used on a job, and must be accurately located on the arbor, the use of a collar such as here shown is quite valuable. The collar is made in three pieces, the width "F" being obtained by movement of the screw "B" in the nut "A," the collar being rigidly locked by means of lock-nut "C." The split bushing "D" is placed on the shaft so that adjustable collar will revolve freely while cutters move endwise over the key "E."

Adjustable distance collar for milling machine arbors.

MILLING SMALL RACKS

An interesting method of constructing a small cutter, for milling small brass racks, is shown herewith. The cutters "C" were made from sheet cast steel, bored, turned and teeth milled and backed off. After hardening, the cutters were assembled on the arbor "A," the intervening distance pieces "L" being made of sheet metal of a gauge pitch when firmly secured in position. In cutting the keyway, allowance was made so that teeth of cutters would be staggered when assembled. "R" shows the rack, and to the right is seen the method of holding a number in a small vise while the rack teeth are being cut.

NO ILLUSTRATIONS REQUIRED



By D. A. H.

THE EFFECT of automobile practice upon machine shop and general factory work may be seen in the increasing use of ordinary grease cups in place of the old drilled oil hole. Cups of ⅛ in. and ¼ in. pipe size are the most common and these of sheet steel formed to shape. One objection to grease cups is the squeezing out of grease upon the fingers—it seems to be easier for it to work out through the loosely fitting threads of the cap than to exit through the ⅛ or ¼ hole that is pierced through the thread end. Such is the actual fact; the force exerted by screwing down the cap must overcome the resistance to entering the small hole in the end, must first compress and then finally push along any other grease in the bearing which is very apt to be hard and mixed with grit. Naturally, a line of least resistance is out under the cap.

If that little exit hole is drilled out to double its size, it will be found that the grease then follows the path that was intended, better lubrication results, and the unpleasant smeariness disappears. This grease cup trouble is most noticeable at locations where the movement is slight, such as rocker pins and shackles and center bolts, and not enough friction is generated to soften the grease.

A Hint About Bolts and Nuts

Planers, boring mills, drill presses, and millers have a bolt problem, all their own. We make a practice of going over these bolts periodically—sawing off poor threads to an even inch length shorter, dieing the bruised threads, and straightening bent bolts. They are returned to the rack with good nuts on and threads oiled. In spite of instructions to the contrary, machine hands are prone to put their full strength on a nut which is not all the way of a bolt—and this practice is hard on bolts and nuts. All the nuts on one machine are of the same size and we furnish a case hardened solid wrench to

Built-up gang cutter for milling small brass racks.

fit those nuts. In going over the bolts, the nuts are examined also. A poor thread condemns a nut. A nut with half-striped thread will ruin a number of bolts, and voce versa. We found it difficult to keep poor nuts from creeping back into service, either on the same size of bolt or tapped out a size larger. A re-tapped nut immediately slows up the machine hand for he then has two sizes to contend with and wastes time hunting or borrowing extra wrenches.

We adopted the plan of drilling the threads out of old nuts using a drill of the next larger bolt size—as a ¾ in. drill for a discarded ⅝ in. nut. The nuts were then put back in service for packing pieces and collars. Used as collars, they take the place of the heterogeneous collection that once filled the spaces between clamps and nuts and, having faced surfaces, there is now less bending of bolts and clamps. Drilled in this way there is little danger of the nuts being again tapped out for even an apprentice would not try to make a ⅞ in nut out of a ⅝ in. body.

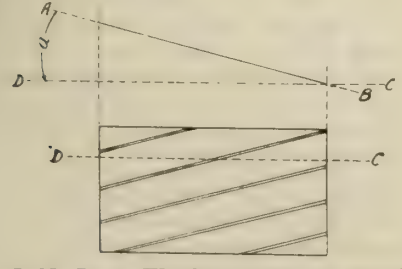
Pipe Threading Practice

Pipe threads taper ¾ in. in diameter per foot of length. Although special machinery is used to considerable extent in threading cast iron fittings, the largest part of this work over 6 in. is done on lathes, thread cutting with chasers. The lathe makers supply manufacturers with headstocks that are built "set over" to half the taper and this produces the correctly tapered thread with the normal carriage travel. An interesting variation from this practice is followed by at least one pipe fitting manufacturer. His lathes are set to produce a finished thread tapered ½ in. to the foot. Then he gets the rest of the taper by setting the chasers at an angle of ⅛ in. to the foot instead of parallel to the line of travel of the carriage. The theory is that the extra scraping of the chasers tilted thus produces a better finish on the thread—and the product seems to bear this out.

Repairing a Chuck

A good 14 in. combination lathe chuck had been cracked through some carelessness—cracked clear across the face and the two edges. It was decided to try and repair the chuck by shrinking on a steel bar the full width of the edge. Accordingly one was made of ½ in. x 3 in., bored with an allowance of 0.003 in. per inch of diameter, and shrunk in place, wrench holes having first been drilled. The result was a true running chuck and one that appears as strong as in the original.

LARGE PULLEYS OFTEN HELP

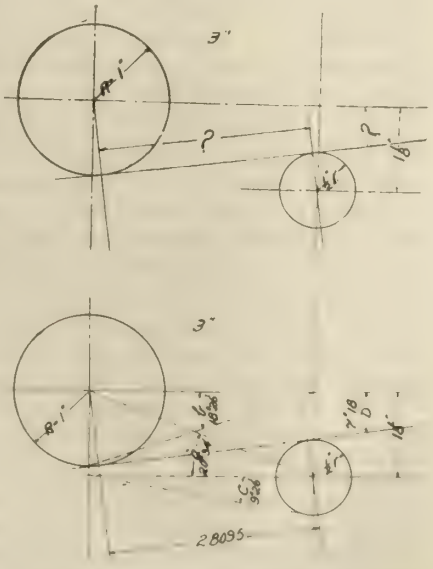


The belt reaches the shaft pulley. The strain drops to almost nothing and it runs back slack to the machine pulley. But, if this machine is not running smoothly, the belt is alternately let down and tightened up on the slack side, and each tightening makes a sharp sudden strain tending to tear the belt to pieces more and more, the slacker the belt is, acting just like a whip in its sudden tautening. One can readily see how this destroys the belt at fasteners and joints.

The size of the pulleys makes a difference in favor of belt service. The larger they are the less the strain and the better they hug the additional length of pulley surface. If a belt on 5-inch pulleys breaks down frequently, the pull on the same belt running over 10-inch pulleys will be just one-half, and the pulley adhesion just twice as great. Of course, the speed of the belt may be used on the enlarged pulleys to convey still more power, if necessary, where such a double belt would quickly wear out on small pulleys.—Belts.

Have You Ever Met Problems Like These?

TOOLROOM PROBLEMS



"Is there any method of finding the head of a spiral milling cutter," asks a reader, "this to be determined from the cutter itself?"

I. N. B. of Windsor, sends us the following solution. In order to determine the head it is first necessary to find the angle between the teeth and the axis of the cutter. Wrap a piece of plain white paper around the cutter and rub the cutting edge of one of the teeth with the handle of the file. This will make an impression on the paper which will be a straight line A-B when the paper is taken from the cutter. With the paper lying flat, draw the line D-C at right angles to the "roll" of the paper, this line D-C representing the axis of the cutter. Measure this angle with a protractor. Suppose the angle to be 15 degrees, the cotangent will be 3.732. This, multiplied by the circumference of the cutter gives the head. With a cutter 2½ in. diameter and angle "a" 15 dedegrees the head would be 2½ x 3.1416 x 3.732=29.3 inches, or one turn in 29-3/10 inches.

"Can the distance between the points of tangency on a line with the circles shown in the accompanying sketch be calculated?" asks a toolroom reader. "It is also desired to find the angle formed by the line of tangency with the horizontal line. How can these dimensions be found?"

I. N. B. of Windsor, sends us the answer herewith. First determine the angles a, b and c. Angle "a" is found by dividing the distance 1⅛ inches by the horizontal centre distance 3 inches, obtaining .375 the tangent of the angle, which form a table is seen to be 20 degrees 34 min. Angle "b" is found in a similar manner; 1 divided by 3 equalling .333, this being the tangent of angle 18 deg. 26 min. Likewise, the angle "c" is found to be 9 deg. 26 min., the tangent .166 being derived by dividing .5 by 3.

Angle of tangency or angle "D" equals (ang. "b" + ang. "c") — angle "a," or 7 deg. 18 min. Sine of angle "D" x 1 + sine of angle "D" x .5 = .1905 in. Horizontal centre distance 3 in. — .1905 in. equals 2.8095 in., distance between points of tangency.

* * *

We all have problems at some time or other, some of which we cannot solve. This department is being created to act as a clearing house for ideas, and co-operation of every reader is requested. The maximum benefit can only be derived through an interchange of opinions.

Have you a problem which is yet unsolved? Or have you solved some difficult proposition, which you believe others would like to hear about?

If you can answer "Yes" to either of these queries, then by all means send your story in to the Editors of Canadian Machinery. They will not only thank you for the interest shown, but will pay for all accepted ideas. Every plant has its problems. We expect a regular deluge of replies. See that we are not disappointed.

The Editors.

New Things in Shop Equipment

HYDRAULIC FORCING PRESS

A hydraulic press that is intended especially for forcing, pressing and bending operations in railroad and large machine shops has recently been placed on the market. The design of the press is that of the reversed cylinder type. The pump that is used in connection with the press, is only employed to actually supply the pressure, as a handwheel is used to quickly bring the ram to and from the work. The press is provided with gauges which indicate the pressure in tons. The press is manufactured by the Watson-Stillman Co. of New York City.

SQUARE ANVILS FOR FORM GAUGES

For some time past a truss form of snap gauge has been marketed, but this gauge is now appearing on the market with large square head anvils. The adjustment and locking devices are the same as employed with the other types of heads, namely two opposed headless set screws working in the frame pulling against each other. The desirable feature of a square anvil is that it permits of working up to a shoulder and gives a larger wearing surface. This square anvil is interchangeable with the round head type, thus new anvils may be substituted at any time. These gauges are manufactured by Pratt & Whitney Co., of Hartford, Conn.

FURNACES, BURNERS AND FORGES

A new line of burners, furnaces and forges has recently been placed on the market. The general design of these products is for the general run of shop work. It includes high-pressure, high-and-low pressure, and intermediate pressure burners. There is also a portable oil burning rivet forge which employs compressed air for atomization, an oil fired furnace that is designed for use in tempering punches, dies, tools and knives; a crucible furnace that employs either gas or oil as fuel, and intended for use in a variety of ways such as lead or cyanide hardening, soft metal melting, tinning baths and galvanizing; a forge for use in welding and miscellaneous forging work; and a furnace for handling of large forging work. The above products are manufactured by the Chicago Flexible Shaft Co., Chicago, Ill.

PORTABLE TAPER BORING BAR

A portable boring bar which has been developed primarily for taper boring operations has recently been placed on the market by the Pedrick Tool and Machine Co., Philadelphia, Pa. The design is such that straight boring operations can also be taken care of as well as tapered boring. The most interesting features of the tool lie in its portability, and its adjustability to suit any taper. The bar is equipped with two cross-heads upon which the same is supported on the part being machined. These cross-heads each have four adjusting set-screws which permit of the final and accurate centering of the bar. By preventing the hand wheel operating, constant and automatic feed may be brought into use, and gearing of the device may be driven by belt, electric motor or air drill. When a facing arm is used with the boring bar, the latter is held by spiders inserted in the bore of the work.

SPIRAL FLUTED EXPANSION REAMERS

A line of spiral fluted expansion hand reamers has recently been developed and placed on the market. All the desirable features of the ordinary straight fluted adjustable reamer as to range of sizes are contained in the new tool, and the advantage lies in the free and clean cutting qualities of the spiral fluted tool. These reamers are equipped with a lock nut to hold the size, and a safety stop which prevents over expansion, and indicates positively when the maximum limit has been reached. They can be obtained in all regular sizes. One of the distinct advantages of the spiral fluted tool is that holes with keyways can be reamed, with the same accuracy as a plain hole. These reamers are manufactured by Messrs. Pratt & Whitney of Hartford, Conn.

LARGE TRILOCK PLUG GAUGES

Some time ago references were made to the construction of large plug gauges made hollow for lightness. Such gauges are now on the market, manufactured in sizes of 2½ in. diameter and larger. The hollow construction feature applies particularly to the "Go" plug being lightened by a web and flange construction. This plug is of wider face than the "No Go" plug and therefore this feature of design is useful only at this point. Two disc type rings are forced into the "Go" plug from opposite ends of same, and into a tapped bore. This is done before grinding. These rings grip the central tube and hold the parts securely together. This provides a means of reversing the "Go" plug, or changing it end for end on its own end of the central tube. This reversible feature provides unusual wearing surface. Three prongs on the handle are forced into three grooves in the bushing, providing a three point self-centering tripod support, without rock or shake, the usual trilock method. A washer at one end and the handle at the other end bear on both the stay tube and the discs, binding the assembled gauge head to the handle. The gauge plugs are of course renewable, as well as reversible. These gauges are manufactured by the Pratt & Whitney Co. of Hartford, Conn.

AUTOMATIC THREADING LATHES

To meet the demand for increased production on automatic threading machines a new type of machine has recently been developed that is capable of taking extra heavy cuts. It is equipped with a geared head that will drive the work for anything from .002 to .020 in. chip feed per cut. Friction drive is replaced by positive clutch drive control on the back shaft. Tool slides have been broadened to accommodate heavier cuts and higher speeds. Tooling arrangements have also been improved. These machines are being manufactured by the Automatic Machine Co. of Bridgeport, Conn.

SPARK PLUG GAUGES

A new set of limit spark plug thread gauges is being placed on the market at the present time. It is made to S. A. E. standard limits and consists of a double end limit plug gauge of the Trilock reversible end type, a "Go" and "No Go" templet in one unit and a setting plug for the templet, consisting of two threaded members and one cylindrical plug for checking root diameter. The pitch diameter of the plugs are .841 in. and .843, the tolerance for tapped holes being .002 in. The templet pitch diameters are .836 in and .839 in., giving .003 tolerance on spark-plug body threads, and a neutral zone of .002 in. between maximum plug and minimum hole. The templet is of the improved adjustable type. The taper screw permits very fine adjustment of pitch diameter and when both locking and adjusting screws are tight the threads of the adjusting screw form a perfect dowel in both planes. The "Go" and "No Go" ends are placed very close together, for convenience in spinning onto work, and the unit is handled more readily than two separate templets, either handled separately or secured together, as is usual when gauging to limits. The "go" side of the templet is cut away for quick identification when using the gauge for rapid inspection. The reversible plug ends provide double the usual wearing surface. These gauges are manufactured by The Pratt & Whitney Co., of Hartford, Conn.

WATCHMAKER'S DRILL CHUCK

A tiny chuck designed for use on watchmakers' lathes and jewelers' drilling machines is a recent development in small tools. It is also for use in multiple drilling and tapping operations on these small sized machine tools. The

chuck is designed to hold drills as small as No. 80 which is 0.013 inch in diameter. The chuck has to operate at speeds up to 20,000 r.p.m. in order to obtain the efficient cutting speeds of such small drills. The body of the chuck has been machined with a tolerance of 0.0005 of an inch in order to obtain the correct balance to permit of such high speed operations. The chuck is ⅞-inch outside diameter, 1 5/16 inches maximum over-all length and weighs about two oz. The key or wrench is of the bevel pinion type, the chuck being similar in design to the "Super" type of chuck manufactured by this firm, the Jacobs Drill Chuck Co., of Hartford, Conn.

HAND FEED SURFACE GRINDER

There has been offered on the market a hand feed surface grinder that has, in addition to the swivel arrangement of the plain table, a provision for tilting it. These little grinders are precision machines and take care of a large volume and wide variety of work in the tool room. The tables are provided with "T" slots to accommodate a magnetic chuck, a vise, or other fixtures. An efficient trueing device, conveniently located on the wheel hood, dresses the grinding wheel, straight or at any desired angle, without removing the work from the table. A Radial trueing device which operates from the grinder table can also be furnished. In the new type of machine, provision is made for tilting the table at any desired angle, the apparatus being graduated in degrees. This tilting arrangement does away with the customary shop practice when grinding at vertical angles on a magnetic chuck, of tilting, or blocking up one edge of the chuck. This practice gives an uncertain support to the chuck which is conducive to vibration. The tilting table provides a rigid method of clamping the chuck directly to the solid table. This machine is manufactured by the Wilmarth & Marmon Co., of Grand Rapids, Mich.

SWING CUT-OFF SAW
